Attachment 1. Analytical Results for Routine Monitoring During 2021

Acknowledgements

Many people support the Lawrence Livermore National Laboratory Site 300 Environmental Restoration Project. The dedication and diverse skills of all these individuals have contributed to the ongoing success of the Environmental Restoration Department activities. The editors wish to collectively thank all the contributing people and companies.

1. Introduction

This Compliance Monitoring Report (CMR) summarizes the Lawrence Livermore National Laboratory (LLNL) Site 300 Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) Remedial Action compliance monitoring activities performed during January through December 2021. The report is submitted in compliance with the Compliance Monitoring Plan (CMP)/Contingency Plan (CP) for Environmental Restoration at Lawrence Livermore National Laboratory Site 300 (Dibley et al., 2009a) and CMP/CP Addendum (MacQueen et al., 2013).

Compliance monitoring activities performed during January through June 2021 were summarized in the First Semester 2021 CMR (Buscheck et al., 2021). As noted in this report, although there was a significant improvement in personnel availability in 2021 as the pandemic situation improved, there were instances where sufficient personnel were not available to complete all required groundwater sampling and analysis per the CMP sampling and analysis requirements during the year. However, the vast majority of CMP monitoring requirements were met in 2021.

During 2021, approximately 6.9 million gallons (gal) of groundwater and 77 million cubic feet (cf) of soil vapor were treated at Site 300, removing approximately 7.7 kilograms (kg) of volatile organic compounds (VOCs), 57 grams (g) of perchlorate, 1,156 kg of nitrate, 84 g of Research Department Explosive (RDX), 0.68 g of TBOS (tetrabutyl orthosilicate)/TKEBS (tetrakis (2-ethylbutyl) silane), and 2.6 g of uranium (Table Summ-1).

Since remediation began in 1991, approximately 479 million gal of groundwater and over 1.43 billion cf of soil vapor have been treated, removing approximately 642 kg of VOCs, 1.9 kg of perchlorate, 23,442 kg of nitrate, 3.0 kg of RDX, 9.5 kg of TBOS/TKEBS, and 0.1 kg of uranium (Table Summ-2).

2. Site 300 Monitoring Program

Section 2 presents the monitoring results for the Site 300 remediation systems, groundwater monitoring network, and surface water sampling and analyses. These results are presented and discussed by operable unit (OU) as follows:

- Section 2.1, General Services Area (GSA) (OU 1);
- Section 2.2, Building 834 (OU 2);
- Section 2.3, Pit 6 Landfill (OU 3);
- Section 2.4, High Explosives Process Area (HEPA) (OU 4);
- Section 2.5, Building 850/Pit 7 Complex (OU 5);
- Section 2.6, Building 854 (OU 6);
- Section 2.7, Building 832 Canyon (OU 7); and
- Section 2.8, Site-Wide (OU 8) (Building 833, Building 801/Pit 8, Building 845/Pit 9, and Building 851).

The locations of the Site 300 OUs 1 through 8 are shown on Figure 2-1. Section 3 presents the detection monitoring results and inspection and maintenance summaries for the Pit 1, 2, 3, 4, 5, 6, 7, 8, and 9 Landfills in OU 3, OU 5, and OU 8. Inspection and maintenance of the Pit 7 Drainage Diversion System (DDS) and the Building 850 Corrective Action Management Unit (CAMU) is conducted in OU 5. Site 300 inspection reports and documentation for these locations will be provided to interested parties upon request.

Section 4 contains a discussion of the Risk and Hazard Management Program. Section 5 is a summary of the Data Management Program.

Information for wells or boreholes that were installed or decommissioned during 2021 is presented in Table 2.1. Tables 2.2 and 2.3 show monthly volumes of groundwater and soil vapor extracted and contaminant masses removed, respectively, for July through December 2021. Table 2.4 contains a summary of concentrations and activity concentrations of contaminants of concern (COCs) in groundwater extraction and treatment system influent and effluent between July and December 2021. Treatment facility operations and maintenance issues, and notable events that occurred during 2021, are included in Table 2.5.

Treatment facility pH data collected during the second semester of 2021 are presented in Appendix A. The treatment facility sampling and analysis plans for the first semester of 2022 are presented in Appendix B. The sampling and analysis plan for groundwater and surface water monitoring at Site 300 for all of 2021 is presented in Appendix C.

Appendix C explains deviations from the sampling plan for all the OUs. There are several scenarios when a monitor well may not be accessible during its planned sampling period. DOE/LLNL plans sampling events on a quarterly basis and the sampling coordinator makes every effort to schedule the sampling event when each location is anticipated to be accessible. There are many situations where a sampler may not have access to a well during an entire sampling period. However, samplers will make repeated attempts to access the location until the end of a given sampling period. The access issues can be grouped into four main categories:

Operational restrictions: Site 300 operates multiple programmatic facilities that perform unique experiments. There are explosives, radiation beam, and other "muster" events and corresponding areas that are often activated around these facilities during experiments, limiting access to sampling locations. The duration and size of the muster events and areas vary depending on each experiment. The sampling coordinator incorporates the best available knowledge into the sampling schedule, but the muster schedule is very dynamic.

Wildlife and sensitive habitat restrictions: Site 300 is home to multiple rare, endangered, and threatened species. Access to areas where these populations exist is controlled by the wildlife biologists who ensure that applicable federal and state regulations are enforced. Access to certain locations is often restricted by the presence of wildlife whose behavior and travel patterns are not predictable.

Terrain and weather-related restrictions: The topography of Site 300 consists of a series of steep hills and canyons. Elevation ranges from about 500 feet (ft) above mean sea level (amsl) in its southeast corner to about 1,750 ft amsl in the northwestern area. Sampling locations are typically accessed via dirt roads that quickly become unsafe or unnavigable for travel during and after significant rainfall events. Significant repairs may be required and access to sampling locations can be restricted for extended periods of time. Overgrown vegetation may also temporarily restrict access to springs. Samplers make every effort to reach sampling locations without compromising their safety.

Equipment malfunctions: DOE/LLNL uses a tracking system to monitor the operational status of each monitoring and extraction well, and the equipment in the well (e.g., dedicated submersible pump). When sampling equipment becomes inoperable, it is entered into the WellTrack system to prioritize and track the status of its repair or replacement. The sampling coordinator will schedule well sampling as soon as the repair or replacement is completed.

All groundwater elevation data for 2021 are included in the data tables presented in Appendix D.

A table summarizing current land use controls for the Site 300 OUs, maps of the locations of land use controls for each OU or subarea, and the completed Institutional Control Monitoring Checklist for 2021 are presented in Appendix E.

A summary of 2021 vapor intrusion (VI) indoor air sampling activities, data analysis, and resulting results and reporting for Site 300 buildings is provided in Appendix F.

Appendix G summarizes quality assurance activities that were conducted in 2021. This includes the information regarding the precision, accuracy, representativeness, comparability, completeness, and sensitivity (the "PARCCS" parameters) of the 2021 analytical data presented in this CMR. Analytical laboratory certifications, performance testing, DOECAP assessments, and ERD inspections and assessments are also discussed.

Total VOC isoconcentration contour maps were constructed by contouring the sum of the concentrations of the following VOCs: trichloroethene (TCE); tetrachloroethene (PCE); *cis*-1,2-dichloroethene (*cis*-1,2-DCE); *trans*-1,2-dichloroethene (*trans*-1,2-DCE); carbon tetrachloride (CTET); chloroform (CFORM); 1,1-dichloroethane (1,1-DCA); 1,2-dichloroethane (1,2-DCA); 1,1-dichloroethene (1,1-DCE); 1,1,1-trichloroethane (1,1,1-TCA); trichlorofluoromethane (Freon 11); 1,1,2-trichloro-1,2,2-trifluoroethane (Freon 113); 1,1,2-trichloroethane (1,1,2-TCA); and vinyl chloride. The individual VOCs that comprise these total VOC concentrations are also posted on these maps. VOC concentrations presented in the text are the sum total of the VOCs described above unless a specific VOC is cited. Isoconcentration contour maps and post-only maps for the primary COCs were constructed using second semester 2021 data. Isoconcentration contour maps and post-only maps for the secondary COCs were constructed using first semester 2021 data. To create a snapshot in time, hydraulic capture zones and extents of saturation are based on groundwater elevation data collected during the same semester as the COC data.

For collocated wells, the highest concentration was used for contouring. As a result, in some rare instances, the maximum COC concentrations reported in the text might not agree with the value posted on the contour map. The two values would not agree if the annual maximum concentration sample was collected during a different semester. The two values would also not agree if the maximum concentration sample was collected during the same semester, but during a different quarter. All COC and groundwater elevation maps were constructed using the quarterly sampling data set that contained the most complete geographic coverage for a particular semester. Specific groundwater monitoring data are discussed within each OU section. All groundwater analytical data are included in the data tables presented in Attachment 1.

Hydraulic capture and injection zones are also presented in this report. The capture zones are defined only for extraction and injection wells that were active during the time period when the groundwater elevations were measured. The capture zones are based primarily on the equipotentials for the groundwater elevation contour maps that are presented in this CMR. These equipotential-based CMR capture zones may also differ from the capture zones presented in the Site-Wide Remediation Evaluation Summary Report (SWRESR) (Ferry et al., 2006), because the SWRESR capture zones were estimated using computer models such as WinFlow© or FEFLOW© (Finite Element subsurface FLOW system). As a general rule, the CMR capture zones were extended to two upgradient groundwater elevation contours. For cases where there were few observation wells located nearby, a

Thiem solution for steady-state radial flow in the vicinity of a pumping well was used to control the groundwater elevation contours. In accordance with the 2009 CMP/CP requirements, hydraulic capture and injection zones are displayed on groundwater elevation contour maps, and primary and secondary COC isoconcentration contour maps for all OUs where active groundwater remediation was occurring in 2021 (i.e., OU 1, OU 2, OU 4, OU 5, OU 6, and OU 7), with one exception. Although treatment was active in OU 5 in 2021, capture zones are not depicted on its water elevation and COC contour maps, as the calculated capture zones are the same scale or smaller than the well symbols depicted on the maps. As previously mentioned, hydraulic capture zones are based on groundwater elevation data that were collected during the same semester that the COC data were collected.

In this report, concentrations for most compounds are reported in micrograms per liter (µg/L). The primary exception is nitrate, which is reported throughout this report in milligrams per liter (mg/L) as NO_3.

Every soil vapor treatment system (SVTS) at Site 300 is associated with its nearby groundwater treatment system (GWTS). The condensate that accumulates in these SVE systems is automatically conveyed and treated at the corresponding adjacent GWTS. DOE/LLNL has contingency plans for treating the condensate at a compatible GWTS, if the adjacent GWTS is idle due to freeze protection or for other reasons. The Building 833 sub-slab depressurization system (SSDS), which does not have a corresponding GWTS for its area, generates condensate that is collected and treated at the Building 815-Source (815-SRC) GWTS.

2.1. General Services Area (OU 1)

The General Services Area OU consists of the Eastern and Central GSA (EGSA and CGSA) areas.

Eastern General Services Area

The source of contamination in the EGSA was abandoned debris burial trenches that received craft shop debris. Leaching of solvents in the debris resulted in the release of VOCs to groundwater. A groundwater extraction and treatment system operated in the EGSA from 1991 to 2007 to remove VOCs from groundwater. VOC-contaminated groundwater was extracted from three wells (W-26R-03, W-25N-01, and W-25N-24) located downgradient of the debris burial trenches at a combined average flow rate of 45 gal per minute (gpm).

Remediation efforts in the EGSA successfully reduced concentrations of TCE and other VOCs in groundwater to below their respective maximum contaminant level (MCL) cleanup standards set in the GSA Record of Decision (ROD) (United States [U.S.] Department of Energy [DOE], 1997). The EGSA groundwater extraction and treatment system was shut off on February 15, 2007, with approval from the U.S. Environmental Protection Agency (EPA), Central Valley Regional Water Quality Control Board (RWQCB), and California Department of Toxic Substances Control (DTSC). As required by the GSA ROD, groundwater monitoring was conducted for five years after treatment facility shutdown to determine if VOC concentrations increased or "rebounded" above MCL cleanup standards. The results of this monitoring indicated that VOC concentrations had remained below MCL cleanup standards during the five-year post-shutdown monitoring period. These results were presented at the February 24, 2012, Remedial Project Managers (RPM) meeting. The regulatory agencies agreed that cleanup of the EGSA was complete, monitoring and reporting could cease, and close-out

documentation should be submitted. The final close-out document was submitted to the regulatory agencies on June 26, 2017 (Ferry et al., 2017).

Central General Services Area

At the CGSA, chlorinated solvents, primarily TCE, were historically used as degreasing agents in craft shops, such as at Building 875. Rinse water from degreasing operations was disposed of in dry wells. Typically, the dry wells were gravel-filled borings approximately three to four ft deep and two ft in diameter. The CGSA dry wells were used until 1982; in 1983 and 1984, these dry wells were decommissioned and excavated.

The CGSA GWTS has been operating since 1992, removing VOCs from groundwater. The CGSA GWTS was off-line for planned system and wellfield upgrades between December 2016 and October 2019. The facility was off-line for most of the first semester of 2021 due to various freeze protection and mechanical issues, and was operated from June through November 17, 2021, when it was secured again for freeze protection. The CGSA GWTS also treats water from the 830-Distal South (830-DISS) facility, which was off-line for most of the first semester of 2021 due to freeze protection and mechanical issues with the CGSA GWTS. The current CGSA GWTS configuration includes particulate filtration, air stripping to remove VOCs from extracted water, and granular activated carbon (GAC) to treat vapor effluent from the air stripper. Treated groundwater is discharged to the surrounding natural vegetation using misting towers. A map of the CGSA showing the locations of monitor and extraction wells, and treatment facilities is presented on Figure 2.1-1.

The CGSA SVTS began operation in 1994, adjacent to the Building 875 dry well contaminant source area, removing VOCs from soil vapor. The SVTS was off-line for system upgrades between December 2016 and September 2018. The CGSA SVTS was online for most of 2021. The SVE wellfield now consists of six wells (W-7I, W-875-07, W-875-08, W-875-09, W-875-11, and W-875-15) with an estimated combined total flow rate of approximately 26 standard cubic ft per minute (scfm). When the CGSA GWTS is operating, simultaneous groundwater extraction in the vicinity lowers the elevation of the water table and maximizes the volume of unsaturated soil influenced by vapor extraction. The SVTS configuration includes a water knockout chamber, a rotary vane blower, and four 140-pound vapor-phase GAC vessels arranged in series. Treated vapors are discharged to the atmosphere under a regulatory permit from the San Joaquin Valley Air Pollution Control District (SJVAPCD).

As discussed in the 2016 Annual CMR (Buscheck et al., 2017a), the plan to convert the CGSA-North GWTS to an extraction-only system was approved and completed on October 17, 2017. Since then, water at the CGSA-North GWES (groundwater extraction system) is extracted from the single extraction well, W-CGSA-2708, and collected in a portable tank. The extracted water in the tank is transferred to the CGSA GWTS for treatment and disposal once the tank becomes full.

2.1.1. GSA Groundwater and Soil Vapor Extraction and Treatment System Operations and Monitoring

2.1.1.1. GSA Compliance Summary

The Central GSA GWTS was off-line for most of the first semester of 2021 due to wintertime freeze protection through mid-April and equipment failure that was resolved in June. While operational from June until November 17, when it was secured for winter freeze protection, it operated in

compliance with the RWQCB substantive requirements for wastewater discharge. The CGSA SVTS system operated in compliance with the SJVAPCD air permit requirements during the duration of the reporting period. The CGSA-North extraction and collection system has no compliance monitoring requirements.

The CGSA treatment facility sampling and analysis plan complies with the monitoring requirements in the CMP/CP. The treatment facility sampling and analysis plan for the first semester of 2022 is presented in Appendix B. No modifications were made to the plan during this reporting period. However, as discussed above, the CGSA-North is now a groundwater extraction and collection system. Therefore, the only sampling is associated with the extraction well to track contaminant mass removal.

2.1.1.2. GSA Operations and Maintenance Issues

Information concerning CGSA and CGSA-North facilities operations and maintenance issues is presented in Table 2.5.

2.1.1.3. GSA Facility Performance Assessment

The monthly groundwater volumes extracted, soil vapor volumes extracted, and operational hours for the second semester of 2021 are summarized in Table 2.2. The total volumes of groundwater and vapor extracted and treated, and masses removed during the reporting period are presented in Table Summ-1. The cumulative volume of groundwater treated and VOC masses removed are summarized in Table Summ-2. Analytical results for influent and effluent water samples are presented in Table 2.4. The pH measurements are presented in Appendix A. Because groundwater treatment is not conducted at CGSA-North, effluent samples and pH measurements were not collected.

During the second semester of 2021, the CGSA SVE system extracted 6,503,000 cf of soil vapor. During the second semester of 2021, the CGSA GWTS system extracted approximately 212,800 gal of groundwater (Table 2.2).

The CGSA-North groundwater extraction and collection system operated as expected during the second semester of 2021 and extracted approximately 80 gal of groundwater. Due to extremely low yield from the single extraction well, the system must be shut down and drained when there is any threat of freezing temperatures, to prevent freeze damage and potential spills of untreated water. It is also routinely shut down to allow the extraction well to recover for quarterly compliance sample collection.

2.1.1.4. GSA Treatment Facility and Extraction Wellfield Modifications

The CGSA GWTS and SVTS have been recently upgraded; as such, no modifications were needed in 2021.

2.1.2. GSA Groundwater Monitoring

The sampling and analysis plan for groundwater monitoring at the CGSA for the entire year is presented in Appendix C. This table explains deviations from the sampling plan. The sampling and analysis plan for the three Eastern GSA off-site water-supply wells and the three Eastern GSA wells retained for CMP monitoring downgradient of the CGSA has been incorporated into Appendix C.

During the reporting period, groundwater monitoring was conducted in accordance with CMP monitoring requirements, with the following exceptions:

1. A total of seven required analyses for seven different wells were not performed because the wells were dry or there was insufficient water for sample collection.
2. A total of three required analyses for two different wells were not performed because of inoperable pumps.
3. A total of two required analyses for two wells were not performed because of inaccessible sampling ports.

Analytical results and groundwater elevation measurements obtained during 2021 are presented in Attachment 1 and Appendix D, respectively.

A groundwater potentiometric contour map for the Qt-$Tnsc_1$ and Qal-$Tnbs_1$ hydrostratigraphic units (HSUs) is shown on Figure 2.1-2.

2.1.3. GSA Remediation Progress Analysis

This section is organized into four subsections: mass removal, analysis of contaminant distribution and concentration trends, remediation optimization evaluation, and performance issues.

2.1.3.1. GSA Mass Removal

The monthly groundwater and soil vapor mass removal estimates for the second semester of 2021 are summarized in Table 2.3. The total mass removed during the reporting period and cumulative mass removal estimates are summarized in Table Summ-1 and Table Summ-2, respectively.

2.1.3.2. GSA Contaminant Concentrations and Distribution

At the CGSA, VOCs are the only COCs in groundwater and soil vapor. TCE is the most prevalent VOC, comprising approximately 90% of the total VOCs (TVOCs). Other VOC COCs include PCE; *cis*-1,2-DCE; *trans*-1,2-DCE; 1,1-DCA; 1,1-DCE; 1,1,1-TCA; 1,1,2-TCA; Freon 11; Freon 113; benzene; bromodichloromethane; CFORM; and vinyl chloride. The hydrostratigraphic units (HSUs) in the CGSA are the Qt-$Tnsc_1$ HSU (western part of CGSA), the Qal-$Tnbs_1$ HSU (eastern part of CGSA), and the underlying Upper and Lower $Tnbs_1$ HSUs.

For the Qt-$Tnsc_1$ and Qal-$Tnbs_1$ HSUs, an isoconcentration contour and individual concentration map for TVOCs, based on second semester of 2021 data, is presented on Figure 2.1-3. Because each CMR map is representative of contaminant concentrations during a particular semester, the maximum concentrations shown on the CMR map may not match the maximum concentrations for 2021 described in the text.

General trends of VOC concentrations in OU 1 include the following:

1. The historical maximum TVOC concentration in groundwater was 272,000 µg/L in March 1992, detected in a bailed sample collected from well W-875-07 during drilling.
2. TVOCs decreased to a current 2021 maximum of 650 µg/L in April, detected in dual extraction well W-7I.
3. The historical maximum TVOC soil vapor concentration was 603 parts per million on a volume per volume basis ($ppm_{v/v}$) in November 1999 in dual extraction well W-875-07.
4. TVOCs decreased to a current 2021 maximum of 5.9 $ppm_{v/v}$ in June in dual extraction well W-7I.

Dry Well Pad Area

The center of mass of the CGSA VOC plume in the Qt-$Tnsc_1$ and Qal-$Tnbs_1$ HSUs is located in the Building 875 dry well pad area, where the highest VOC and TCE concentrations continue to occur in the Qt-$Tnsc_1$ HSU. All of the wells in this area were sampled, as scheduled, during the reporting period, except for SVE well W-875-10, which was dry in March, May, and November, and was not sampled during the third quarter of 2021 due to insufficient personnel availability due to the COVID-19 pandemic. While TCE is the major VOC detected in the Building 875 dry well area, other VOCs typically detected in this area have included PCE; *cis*-1,2-DCE; 1,1-DCE; *trans*-1,2-DCE; 1,1-DCA; and 1,2-dichloroethane (1,2-DCA). Of these VOCs, only TCE, PCE, and *cis*-1,2-DCE have generally been present at concentrations that significantly exceed their MCL cleanup standards, while 1,2-DCA has been detected at or near its MCL cleanup standard of 0.5 µg/L.

Overall, a decreasing trend of VOC concentrations in groundwater continues in the dry well pad area. For example, TCE concentrations have decreased from a historical maximum of 240,000 µg/L in dual extraction well W-875-07 (1993) to a current 2021 maximum of 570 µg/L (April) in dual extraction well W-7I. PCE concentrations have decreased from a historical maximum of 25,000 µg/L (1993, well W-875-07) to a current 2021 maximum of 33 µg/L (April, well W-7I); *cis*-1,2-DCE concentrations have decreased from the 1993 historical maximum of 16,000 µg/L in dual extraction well W-7I to a current 2021 maximum of 86 µg/L (September) in dual extraction well W-875-08. 1,1-DCA concentrations have decreased from the 1993 historical maximum of 38 µg/L (well W-7I) to below the 5 µg/L MCL cleanup standard, at 0.66 µg/L (well W-7I, April 2021). Concentrations of 1,1-DCE have decreased from a historical maximum of 860 µg/L (well W-7I, 1993) to a current 2021 maximum of 5.6 µg/L (well W-7I, April).

In 2021, TCE soil vapor concentrations in wells W-875-07, W-875-08, W-875-09, W-875-11, and W-875-15 ranged from 0.0095 to 1.1 $ppm_{v/v}$, with the highest concentration occurring in dual extraction well W-875-09 in September. These vapor concentrations have decreased significantly from the historical maximum TCE concentration of 530 $ppm_{v/v}$ detected in extraction well W-875-07 in 1994.

Outside the Dry Well Pad Area

Outside the Building 875 dry well pad area, wells monitor the Qt-$Tnsc_1$, Qal-$Tnbs_1$, Upper $Tnbs_1$, and Lower $Tnbs_1$ HSUs. The overall spatial distribution of VOCs in groundwater downgradient of the Building 875 dry well pad source area did not change significantly during 2021.

Qt-$Tnsc_1$ and Qal-$Tnbs_1$ HSUs

For monitor wells outside the dry well pad area and screened in the Qt-$Tnsc_1$ and the Qal-$Tnbs_1$ HSUs, the historical maximum TVOC concentration was detected in well W-7O (screened in the Qt-$Tnsc_1$ HSU) at 920 µg/L (1994). The current 2021 maximum of 275 µg/L (August) was detected in the same well. In addition to TCE, other VOCs detected during the reporting period include PCE; *cis*-1,2-DCE; 1,1-DCE; and Freon 11. Of these VOCs, only TCE is typically present above its MCL cleanup standard of 5 µg/L. However, in three samples from monitor well W-7O, PCE was also detected slightly above its MCL cleanup standard of 5 µg/L at 12 µg/L, 14 µg/L, and 18 µg/L in March, April, and August 2021, respectively.

Upper $Tnbs_1$ HSU

Five monitor wells (W-7A, W-7B, W-7C, W-7E, and W-7N) are screened in the Upper $Tnbs_1$ HSU. No VOCs were detected above reporting limits in these wells during 2021. Concentrations of VOCs above reporting limits have not been detected in these wells since 2012.

Lower $Tnbs_1$ HSU

Five monitor wells (W-873-01, W-7G, W-7K, W-7L, and W-7M) are screened in the deeper Lower $Tnbs_1$ HSU. The historical maximum TVOC concentration in this HSU was detected in well W-7G at 47 µg/L (mostly TCE, 1989). No VOCs were detected above reporting limits in these wells during 2021. Vinyl chloride was detected at 0.54 µg/L in a sample taken from well W-7G in December 2019. In addition, a TVOC concentration of 13.8 µg/L, comprised of 11 µg/L of TCE and 2.8 µg/L of *cis*-1,2-DCE, was detected in well W-873-01 in December 2017. This well was installed in 1988 and except for the one-time detection in 2017, VOCs had never been detected above reporting limits in well W-873-01. VOCs were not detected in subsequent samples from the well taken in 2018 through 2021. Wells W-873-01 and W-7G will continue to be monitored closely. Except for the December 2017 detections, VOCs had not exceeded their respective reporting limits in Lower $Tnbs_1$ HSU CGSA wells since 2001.

South of the Site 300 Boundary

South of the Site 300 boundary, 17 wells monitor the Qt-$Tnsc_1$ HSU, Upper $Tnbs_1$ HSU, and Lower $Tnbs_1$ HSU.

Qt-$Tnsc_1$ HSU

During 2021, TVOC concentrations were detected above reporting limits in two Qt-$Tnsc_1$ HSU off-Site 300 monitor wells, W-35A-01 at 21.7 µg/L (December, comprised of 20 µg/L of TCE, 1.2 µg/L of PCE, and 0.5 µg/L of Freon 11) and W-35A-10 at 8.9 µg/L (November, comprised of 5.6 µg/L of TCE and 3.3 µg/L of Freon 11). TVOC concentrations of 10 µg/L were also detected in well W-35A-10 in June, whereas well W-35A-01 did not have sufficient water for sample collection during the same event. The historical maximum TVOC concentration observed in Qt-$Tnsc_1$ HSU groundwater south of the Site 300 boundary was detected in 1991 in well W-35A-01 at 545 µg/L (comprised of 510 µg/L of TCE, 32 µg/L of PCE, and 3 µg/L of 1,1-DCE). During the reporting period, no VOCs were detected above their reporting limits in the remaining Qt-$Tnsc_1$ HSU CGSA wells located south of the Site 300 boundary.

Upper $Tnbs_1$ HSU

During 2021, VOCs were not detected in the three monitor wells (W-35A-05, W-35A-12, and W-35A-13) screened in the Upper $Tnbs_1$ HSU, south of the Site 300 boundary. VOCs were last detected in this HSU in 2006 (0.59 µg/L of TCE, W-35A-13).

Lower $Tnbs_1$ HSU

Five Lower $Tnbs_1$ wells are located south of the Site 300 boundary. A monthly groundwater sample collected in December 2021 from water-supply well CDF1 yielded low concentrations of vinyl chloride at 0.69 µg/L in the duplicate sample and 0.52 µg/L in the routine sample. Because vinyl chloride has never been detected above the 0.5 µg/L reporting limit in the sampling history of the well back to 1987, the well was resampled in early January 2022; the resulting data will be reported in the first semester 2022 CMR. This well will continue to be monitored for future trends.

VOCs were not detected above their reporting limits in the other four Lower $Tnbs_1$ CGSA wells located south of the Site 300 boundary. Except for the low vinyl chloride concentrations reported in samples from water-supply well CDF1 in December, VOCs have not been reported in this HSU since January 2014, when 0.81 µg/L of CFORM was detected in well CDF1.

2.1.3.3. GSA Remediation Optimization Evaluation

The CGSA GWTS extracted 239,208 gal of groundwater and removed 39 g of VOC mass during 2021 (Table Summ-1). During 2021, the CGSA SVTS extracted approximately 12,827,000 cf of soil vapor and removed 184 g of VOC mass. A total of 130 gal of groundwater and 0.0025 g of VOC mass were extracted and removed at CGSA-North during 2021. Table Summ-2 lists the mass removed by each individual treatment facility over its operational history. Table 2.2 shows the volumes of groundwater and soil vapor treated and discharged and each of the facilities' operational hours for the second semester of 2021.

Static water levels measured in GSA groundwater wells in 2021 were lower than those measured in 2020 as a result of the below-average rainfall during the 2020-2021 winter season. The 2021 water year rainfall total at Site 300 was approximately 40% less than the 2020 total. Water levels in wells that are predominantly screened in the Qal (alluvial channel fill), Qt (terrace alluvium), and weathered bedrock were approximately 2.5 ft lower than those observed in 2020. Water levels in wells that are primarily screened in bedrock (e.g., Upper $Tnbs_1$, Lower $Tnbs_1$, and $Tnsc_1$ HSUs) were approximately 1.5 ft lower on average than those observed in 2020.

Groundwater extraction at the CGSA GWTS continues to capture groundwater with the highest VOC concentrations. Remediation efforts have reduced TVOC concentrations in CGSA groundwater from a historical maximum of 272,000 µg/L in a bailed groundwater sample that was collected during the drilling of well W-875-07 (1992) to a current 2021 maximum of 650 µg/L (well W-7I, April). At the eastern edge of the VOC plume, VOC concentrations continue to decrease and remain below MCL cleanup standards in monitor wells W-26R-06 and W-26R-11.

Groundwater remediation continues to reduce VOC concentrations in two key off-site performance monitor wells, W-35A-01 and W-35A-10, located within 50 and 100 ft of the southern site boundary, respectively. Analysis of recent data from operating extraction wells shows that well W-35A-01 may be within the hydraulic capture zone of CGSA extraction well W-875-08. TVOC concentrations in well W-35A-01 have decreased from the historical maximum of 545 µg/L (1991) to 21.7 µg/L in December 2021. TCE in well W-35A-01 declined from its historical maximum of 510 µg/L (1991) to 20 µg/L in December 2021 and is currently the only VOC exceeding its MCL cleanup standard in this well. Although well W-35A-10 is likely not within the hydraulic capture zone of the CGSA extraction wellfield, TVOC concentrations continue to exhibit a long-term declining trend due to hydraulic capture of VOCs upgradient of this well. TVOC concentrations in well W-35A-10 declined to 8.9 µg/L in November 2021, down from a historical maximum of 86 µg/L in 1994. TCE concentrations in well W-35A-10 have also declined from a historical maximum of 40 µg/L (1994) to 5.6 µg/L in November 2021, whereas Freon 11 concentrations in this well have declined from a historical maximum of 46 µg/L (1994) to 3.3 µg/L over the same time period. TCE was the only compound detected slightly above its MCL cleanup standard in well W-35A-10 during 2021.

2.1.3.4. GSA OU Remedy Performance Issues

The CGSA GWTS, SVTS, and CGSA-North GWES operated for the majority of the second semester. There were no new issues that affected the performance of the cleanup remedy for the GSA OU. The extent of VOCs in excess of MCL cleanup standards did not change and concentrations decreased overall from those detected in 2020. The remedy continues to be effective and protective of human health and the environment and is making progress toward cleanup.

2.2. Building 834 (OU 2)

The Building 834 area has been used to test the stability of weapons and weapon components under various environmental conditions since the 1950s. Past spills and piping leaks in this OU have resulted in soil and groundwater contaminated with VOCs and TBOS/TKEBS, silicate oils that are co-contaminants with TCE. Nitrate concentrations in Building 834 groundwater that exceed the MCL cleanup standard (45 mg/L) are likely caused by a combination of natural sources and septic system leachate. In addition, prior to 1994, a former underground diesel storage tank released diesel to the subsurface; the tank was excavated and removed in 1994.

The Building 834 OU is informally divided into three areas: the core, leachfield (septic system), and distal areas (Figure 2.2-1). The core area generally refers to the vicinity of the buildings and test cells in the center of the Building 834 area where most of the contaminant releases occurred. The leachfield area is located immediately southwest of the core area. The distal (T2) area refers to the area downgradient (south) of the core and leachfield areas. A map of the Building 834 OU showing the locations of monitor and extraction wells, and the treatment facility is presented on Figure 2.2-1.

The Building 834 GWTS and SVTS began operation in 1995 and 1998, respectively. These treatment systems are in the core area. The GWTS removes VOCs, nitrate, and TBOS/TKEBS from groundwater extracted primarily from the Tpsg HSU, with one well extracting from the deeper Tps-Tnsc$_2$ HSU. The SVTS removes VOCs from soil vapor. Due to the very low groundwater yield from individual extraction wells (<0.1 gpm), the GWTS and SVTS have been operated simultaneously in batch mode. The GWTS can be operated alone. Historically, the SVTS typically has not been operated without concurrent groundwater extraction. If the water table is not sufficiently lowered beneath the screen of each dual extraction well prior to vapor pumping, the rising groundwater can cover the well screen, hampering vapor flow into the well. During this reporting period, the SVTS was successfully operated without concurrent groundwater extraction, for the purpose of mitigating potential VI into nearby buildings.

The current extraction wellfield consists of 13 dual extraction wells, 12 of which extract from the Tpsg HSU, and one well, W-834-2001, which extracts from the deeper Tps-Tnsc$_2$ HSU. Nine extraction wells (W-834-B2, W-834-B3, W-834-D4, W-834-D6, W-834-D7, W-834-D12, W-834-D13, W-834-J1, and W-834-2001) are located within the core area and four wells (W-834-S1, W-834-S12A, W-834-S13, and W-834-2113) are located within the leachfield area. Groundwater is extracted on a cyclic basis because the wells cannot sustain continuous pumping. During this reporting period, extraction was limited; the GWTS remained off throughout the winter season freeze protection period followed by 23 days of operation in April. In early May, a failure of a transfer pump caused the GWTS to remain off through August 11, when it was restarted and operated for 97 days through November 15; at that time the system was taken off-line for freeze protection. The SVTS operated

throughout the entire year and extracted soil vapor at a combined flow rate of approximately 85 scfm. The current GWTS configuration includes hydrocarbon adsorption devices to remove floating TBOS/TKEBS silicate oil and diesel fuel (if present), followed by aqueous-phase GAC to remove VOCs, dissolved-phase TBOS/TKEBS, and diesel fuel from groundwater. Nitrate-bearing treated effluent is then discharged via a misting tower on to the landscape for uptake and utilization of the nitrate by indigenous grasses. The current SVTS configuration includes vapor-phase GAC for VOC removal. Treated vapors are discharged to the atmosphere in compliance with an air permit issued by the SJVAPCD.

Since 2005, a long-term enhanced *in situ* bioremediation treatability test has been conducted at the distal T2 area. This testing has included biostimulation to transform groundwater from oxidizing to reducing conditions and bioaugmentation with KB-1™, a natural non-pathogenic microbial consortium capable of complete dechlorination of TCE to ethene. This long-term test is summarized in Section 2.2.3.4.

2.2.1. Building 834 OU Groundwater and Soil Vapor Extraction and Treatment System Operations and Monitoring

2.2.1.1. Building 834 OU Compliance Summary

The Building 834 treatment facility sampling and analysis plan complies with the monitoring requirements in the CMP/CP. The sampling and analysis plan for the first semester of 2022 is presented in Appendix B. No modifications were made to the plan during this reporting period.

2.2.1.2. Building 834 OU Operations and Maintenance Issues

Information concerning the Building 834 GWTS and SVTS facilities operations and maintenance issues is presented in Table 2.5.

2.2.1.3. Building 834 OU Facility Performance Assessment

The monthly groundwater and soil vapor volumes extracted and operational hours for the second semester of 2021 are summarized in Table 2.2. The total volumes of groundwater and vapor extracted and treated, and contaminant masses removed during the reporting period are presented in Table Summ-1. The cumulative volume of groundwater and soil vapor treated and discharged, and masses removed are summarized in Table Summ-2. Analytical results for influent and effluent water samples collected during the second semester of 2021 are presented in Table 2.4. The pH measurements are presented in Appendix A.

The Building 834 GWTS system operated for 2,283 hours during the second semester of 2021 and extracted 28,160 gal of groundwater (Table 2.2). The Building 834 SVTS system operated for 4,232 hours during the second semester of 2021 and extracted 26,934,000 cf of soil vapor.

2.2.1.4. Building 834 OU Treatment Facility and Extraction Wellfield Modifications

No modifications to the treatment facilities were made during this reporting period.

2.2.2. Building 834 OU Groundwater Monitoring

The status of the 2021 annual groundwater monitoring sampling and analysis at Building 834 is presented in Appendix C. This table also explains deviations from the sampling plan. Analytical results and groundwater elevation measurements obtained during 2021 are presented in Attachment 1 and

Appendix D, respectively. Figure 2.2-2 shows the second semester 2021 groundwater potentiometric surface map for the Tpsg HSU in the Building 834 OU.

During the second semester of 2021, groundwater monitoring was conducted in accordance with the CMP monitoring requirements with the following exception: a total of 38 required analyses for 38 different wells were not performed. Eleven wells were dry or there was insufficient water to collect the samples, 24 required analyses were not performed because of limited personnel availability due to the COVID-19 pandemic, and three required analyses were not performed because the wells were inaccessible.

2.2.3. Building 834 OU Remediation Progress Analysis

This section is organized into five subsections: mass removal, analysis of contaminant distribution and concentration trends, remediation optimization evaluation, treatability study, and remedy performance issues.

2.2.3.1. Building 834 OU Mass Removal

The monthly groundwater and soil vapor mass removal estimates for the second semester of 2021 are summarized in Table 2.3. The total mass removed during 2021 and cumulative mass estimates are summarized in Table Summ-1 and Table Summ-2, respectively.

2.2.3.2. Building 834 OU Contaminant Concentrations and Distribution

At the Building 834 OU, VOCs (primarily TCE, but also PCE; *cis*-1,2-DCE; 1,1,1-TCA; and CFORM) are the primary COCs detected in groundwater. TBOS/TKEBS and nitrate are the secondary COCs. These COCs have been identified in two shallow HSUs: (1) the Tpsg gravel perched water-bearing zone, and (2) the underlying Tps-Tnsc$_2$ perching horizon.

For the Building 834 OU:

- Second semester 2021 individual VOC, TBOS/TKEBS and nitrate concentrations for the Tps-Tnsc$_2$ HSU are posted on Figure 2.2-3.
- Second semester 2021 total VOC isoconcentration contours and individual VOC concentrations for the Tpsg HSU are presented on Figure 2.2-4.
- First semester 2021 TBOS/TKEBS concentrations for the Tpsg HSU are posted on Figure 2.2-5.
- First semester 2021 nitrate concentrations for the Tpsg HSU are posted on Figure 2.2-6.

Because each CMR map is representative of contaminant concentrations during a particular semester, the maximum concentration shown on a CMR map may not match the maximum concentration for 2021 described in the text.

2.2.3.2.1. VOCs Concentrations and Distribution

Although the overall extent of VOCs in Building 834 OU groundwater and soil vapor have not changed significantly, the maximum concentrations have decreased by several orders of magnitude since remediation began in the mid-1990s. The most significant changes in the extent of VOC-contaminated groundwater, especially beneath the core area, have resulted from changes in the extent of saturation. Slightly above-average rainfall and recharge during the 2018-2019 winter season was followed by below-average rainfall and less recharge during the 2019-2020 and 2020-2021 winter

seasons. These changes have slightly reduced the areal extent of saturation and VOCs, mostly in the core area.

VOCs detected in Building 834 area groundwater consist primarily of TCE and *cis*-1,2-DCE. Other VOCs including PCE; 1,1,1-TCA; CFORM; vinyl chloride; 1,1-DCE; 1,1,2-TCA; *trans*-1,2-DCE; Freon 11; Freon 113; and CTET; ethane and ethene have also been detected, albeit at much lower concentrations in recent years.

Since 2004 (including 2021), 1,1,1-TCA has not been observed above its typical reporting limit of 0.5 µg/L in any Building 834 OU wells.

Core Area

The Building 834 core area continues to exhibit high VOC concentrations in groundwater and soil vapor. VOC concentrations and distribution in groundwater and soil vapor in the Tpsg and Tps-$Tnsc_2$ HSUs in the Building 834 core area are discussed below.

Tpsg HSU

The Tpsg HSU in the core area has exhibited declining VOC concentration trends since treatment began in 1995. Twenty-seven wells (19 monitor and 8 dual extraction wells) are screened in the Tpsg HSU in the core area. Significant progress has been made in removing VOC mass from extracted groundwater and vapor. While the spatial extent of VOCs has decreased over time, the highest concentrations continue to occur near core area wells W-834-C5, W-834-D3, W-834-D4, W-834-D5, W-834-D6, W-834-D7, W-834-D13 and W-834-D14.

Concentrations of primary COC VOCs in Tpsg HSU groundwater within the core area are generally declining:

- The historical maximum TVOC concentration is 1,100,000 µg/L, detected in 1988 in well W-834-D5.
- TVOC concentrations have declined to a current 2021 maximum of 8,500 µg/L, detected in March in well W-834-D5.
- The historical maximum TCE concentration is 1,100,000 µg/L, detected in 1988 in well W-834-D5.
- TCE concentrations have declined to a current 2021 maximum of 6,200 µg/L, detected in October in well W-834-D7.
- The historical maximum *cis*-1,2-DCE concentration is 540,000 µg/L, detected in 1990 in well W-834-D4.
- *cis*-1,2-DCE concentrations have declined to a current 2021 maximum of 6,400 µg/L, detected in March in well W-834-D5.
- The historical maximum PCE concentration is 10,000 µg/L, detected in 1993 in well W-834-D3.
- PCE concentrations have declined to a current 2021 maximum of 35 µg/L, detected in October in well W-834-D7.
- The historical maximum 1,1,1-TCA concentration is 33,000 µg/L, detected in 1991 in well W-834-J1.

- 1,1,1-TCA concentrations remained below the typical laboratory reporting limit range of 0.5 to 2.5 µg/L in all core area Tpsg HSU wells during 2021.
- The historical maximum CFORM concentration is 44 µg/L, detected in 2009 in well W-834-1709.
- CFORM concentrations have declined to a current 2021 maximum of 0.96 µg/L, detected in March in well W-834-1709.

In the core area, *cis*-1,2-DCE, vinyl chloride, and ethene are microbial dechlorination products of TCE that appear to be present in portions of the Tpsg HSU that contain TBOS/TKEBS. These silicate oils support long-term dechlorination of TCE. TBOS and TKEBS can slowly hydrolyze abiotically to butanol and ethylbutanol, respectively, and ferment biotically to butyrate and ethylbutyrate, respectively. During fermentation of these alcohols, hydrogen is produced, providing electrons for microbial dechlorinators. Butyrate is an excellent slow-fermenting substrate, producing the hydrogen needed for dehalogenation (Vancheeswaran, 1998; Yu and Semprini, 2002).

Reductive dechlorination is occurring in this area as indicated by the occurrence of vinyl chloride at specific concentrations of:

- 170 µg/L (March) in core area monitor well W-834-D5;
- 63 µg/L (July) in core area extraction well W-834-B3;
- 57 µg/L (February) in core area extraction well W-834-D3;
- 15 µg/L (March) core area extraction well W-834-D4;
- 6.1 µg/L (February) in core area monitor well W-834-D14;
- 0.89 µg/L (March) in core area monitor well W-834-1709; and
- 0.68 µg/L (October) in core area extraction well W-834-D13.

While many bacteria species are capable of the initial step in reductively dechlorinating TCE to *cis*-1,2-DCE, so far, only certain strains of *Dehalococcoides mccartyi (Dhc)* have been found capable of dechlorinating *cis*-1,2-DCE to vinyl chloride and vinyl chloride to innocuous ethene and ethane (Pérez-de-Mora et al., 2018). During 2021, these wells were not sampled for light hydrocarbons (i.e., the dissolved gases ethene, ethane, methane) and volatile fatty acids. However, the most recent sampling for these analytes, conducted in September 2017, yielded ethene concentrations as high as 99 µg/L in monitor well W-834-D3, with lesser concentrations of ethene (ranging from less than the 0.1 µg/L reporting limit to 1.1 µg/L) in the remaining core area wells. A recent oxidation/reduction potential (ORP) measurement of -87 millivolts (mV) (March 2021) in core area well W-834-A1 indicated reducing subsurface conditions were still present although less than observed in previous years. Historically, these data have suggested that complete reductive dechlorination is still occurring in portions of the core area, supported by the presence of TBOS/TKEBS as an electron donor. In general, wells that contained TBOS/TKEBS exhibited the highest concentrations of *cis*-1,2-DCE and vinyl chloride, which accumulate under anaerobic conditions when the SVE system is not operational, such as during winter freeze protection shutdown periods. Concentrations of *cis*-1,2-DCE and vinyl chloride decline once the SVE system is restarted and the subsurface becomes more oxygenated in the summer. During the most recent 2020-2021 winter freeze protection shutdown period, groundwater extraction was suspended while SVE continued.

Also, while not a COC, in 2021, 1,1-DCE was detected above the reporting limit in nine core area Tpsg HSU wells (W-834-B2, W-834-B3, W-834-D3, W-834-D4, W-834-D5, W-834-D7, W-834-D13, W-834-D14, and W-834-1709). Only well W-834-D5 yielded 1,1-DCE in excess of the 6 µg/L MCL cleanup standard with 11 µg/L (March). Other VOCs in core area Tpsg HSU wells (including *trans*-1,2-DCE; 1,1-DCA; 1,2-DCA; 1,1,2-TCA; Freon 11; Freon 113; and CTET) either did not exceed reporting limits or were below their MCL cleanup standards.

During the reporting period, TCE soil vapor concentrations in core area SVE wells ranged from 0.02 to 12 $ppm_{v/v}$. This represents a three-order-of-magnitude decrease from the pre-remediation maximum TCE concentration of 3,200 $ppm_{v/v}$ in 1989 (extraction well W-834-D4). Well W-834-D4 is located about 10 ft from former extraction well W-834-D5, where the historical maximum groundwater VOC concentration in the Tpsg HSU occurred. The highest TCE soil vapor concentration (12 $ppm_{v/v}$) was detected in extraction well W-834-B2 on October 19, 2021, a result representative of pumping conditions.

Tps-Tnsc$_2$ HSU

In the core area, underlying the Tpsg HSU, the Tps-Tnsc$_2$ HSU continues to contain the highest VOC groundwater concentrations in the Building 834 OU and at Site 300. Seven wells (six monitor and one dual extraction wells) are screened in the Tps-Tnsc$_2$ HSU. Progress has been made in removing COC mass in both the aqueous and vapor phases. While the spatial extent of VOCs has decreased over time, the highest concentrations continue to occur near core area wells W-834-2001, W-834-A1, and W-834-U1.

Concentrations of primary COC VOCs in Tps-Tnsc$_2$ HSU groundwater within the core area are generally declining:

- The historical maximum TVOC concentration is 298,000 µg/L, detected in 2012 in well W-834-A1.
- TVOC concentrations have declined to a current 2021 maximum of 187,000 µg/L, detected in March in well W-834-A1.
- The historical maximum TCE concentration is 298,000 µg/L, detected in 2012 in well W-834-A1.
- TCE concentrations have declined to a current 2021 maximum of 150,000 µg/L, detected in March in well W-834-A1.
- The historical maximum *cis*-1,2-DCE concentration is 36,000 µg/L, detected in 2000 in well W-834-D8.
- The current 2021 maximum *cis*-1,2-DCE concentrations of 36,000 µg/L was detected in March in well W-834-A1.
- The historical maximum PCE concentration is 7,900 µg/L, detected in 2001 in well W-834-A1.
- PCE concentrations have declined to a current 2021 maximum of 750 µg/L, detected in March in well W-834-A1.
- The historical maximum CFORM concentration is 42 µg/L, detected in wells W-834-A1 and W-834-U1 in 2000.

- CFORM concentrations have declined to a current 2021 maximum of 26 µg/L, detected in March in well W-834-A1.
- The historical maximum 1,1,1-TCA concentration is 28 µg/L, detected in 2000 in well W-834-A1.
- 1,1,1-TCA concentrations have declined to below the reporting limit range of 0.5 to 2.5 µg/L in all core area Tps-Tnsc$_2$ HSU wells during 2021.

Additionally, while not COCs, vinyl chloride was detected in 2021 at 42 µg/L (February) in well W-834-U1, and 1,1-DCE was detected above the 6 µg/L MCL cleanup standard in one core area Tps-Tnsc$_2$ HSU well (W-834-A1, 160 µg/L, March). Other VOCs in Tps-Tnsc$_2$ HSU wells (including *trans*-1,2-DCE; 1,1-DCA; 1,2-DCA; 1,1,2-TCA; Freon 11; Freon 113; and CTET) were below their MCL cleanup standards during 2021.

During the reporting period, the highest TCE soil vapor concentration from the only core area Tps-Tnsc$_2$ HSU SVE well, W-834-2001, was 0.82 ppm$_{v/v}$ in a sample collected on October 19, 2021, under pumping conditions. The historical maximum TCE vapor concentration from this well is 30 ppm$_{v/v}$ (April 2011), which was representative of rebound conditions following a prolonged period of treatment facility shutdown. Higher vapor concentrations may be observed after an extended rebound period.

Leachfield Area

VOC concentrations and distribution in groundwater and soil vapor in the Tpsg and Tps-Tnsc$_2$ HSUs in the Building 834 leachfield area are discussed below.

Tpsg HSU

The Tpsg HSU in the leachfield area has exhibited declining VOC concentration trends since treatment began in 1995. Six wells (two monitor and four dual extraction wells) are screened in the Tpsg HSU in the Building 834 OU. Progress has been made in removing COC mass in both the aqueous and vapor phases. While the spatial extent of contamination has decreased over time, the highest VOC concentrations continue to occur in the vicinity of leachfield area wells W-834-2113, W-834-S1, and W-834-S13.

Concentrations of primary COC VOCs in Tpsg HSU groundwater within the leachfield area are generally declining:

- The historical maximum TVOC concentration is 179,000 µg/L, detected in 1988 in well W-834-S1.
- TVOC concentrations have declined to a current 2021 maximum of 2,000 µg/L, detected in March in extraction well W-834-2113.
- The historical maximum TCE concentration is 170,000 µg/L, detected in 1988 in well W-834-S1.
- TCE concentrations have declined to a current 2021 maximum of 2,000 µg/L, detected in March in extraction well W-834-2113.
- The historical maximum *cis*-1,2-DCE concentration is 3,900 µg/L, detected in 2003 in well W-834-S13.
- *cis*-1,2-DCE concentrations have declined to a current 2021 maximum of 84 µg/L, detected in October in extraction well W-834-S1.

- The historical maximum PCE concentration is 6,300 µg/L, detected in 1986 in well W-834-S1.
- PCE concentrations have declined to a 2021 maximum of 4.9 µg/L, detected in October in extraction well W-834-S1.
- The historical maximum 1,1,1-TCA concentration is 300 µg/L, detected in 1986 in well W-834-S1.
- 1,1,1-TCA concentrations have declined to below the reporting limit range of 0.5 to 2.5 µg/L, in all leachfield area Tpsg HSU wells during 2021.
- The historical maximum CFORM concentration is 950 µg/L, detected in 1989 in well W-834-S1.
- CFORM concentrations have declined to below the typical reporting limit of 0.5 µg/L, in all leachfield area Tpsg HSU wells during 2021.

Except for October detections of 0.66 µg/L and 0.58 µg/L of 1,1,2-TCA in W-834-S12A and W-834-2112, respectively, other VOCs (including *trans*-1,2-DCE; 1,1-DCA; 1,2-DCA; CTET; vinyl chloride; Freon 11; and Freon 113) did not exceed reporting limits in Tpsg HSU leachfield area wells during this reporting period.

During 2021, TCE soil vapor concentrations ranged from 0.16 to 2.5 $ppm_{v/v}$, significantly lower than the 710 $ppm_{v/v}$ maximum pre-remediation concentration measured in 2004 in leachfield area well W-834-S13. The highest TCE soil vapor concentration (2.5 $ppm_{v/v}$) was sampled in extraction well W-834-2113 on April 20, 2021, a result representative of pumping conditions.

Tps-Tnsc$_2$ HSU

In the leachfield area, the Tps-Tnsc$_2$ HSU has continued to exhibit overall declining VOC concentrations since monitoring began in 1989. The underlying Tps-Tnsc$_2$ HSU, monitored by two wells, W-834-S8 and W-834-S9, exhibits VOC concentrations significantly lower than in the overlying Tpsg HSU or in the core area.

Concentrations of primary COC VOCs in Tps-Tnsc$_2$ HSU groundwater within the leachfield area are generally declining:

- The historical maximum TVOC concentration is 16,000 µg/L, detected in 1992 in well W-834-S8.
- TVOC concentrations have declined to a current 2021 maximum of 3,100 µg/L, detected in February in well W-834-S8.
- The historical maximum TCE concentration is 16,000 µg/L, detected in 1992 in well W-834-S8.
- TCE concentrations have declined to a current 2021 maximum of 3,000 µg/L, detected in February in well W-834-S8.
- The historical maximum *cis*-1,2-DCE concentration is 130 µg/L, detected in 1991 in well W-834-S8.
- *cis*-1,2-DCE concentrations have declined to a current 2021 maximum of 58 µg/L, detected in February in well W-834-S8.
- The historical maximum PCE concentration is 170 µg/L, detected in 1993 in well W-834-S8.

- PCE concentrations have declined to a current 2021 maximum of 34 µg/L, detected in February in well W-834-S8.
- The historical maximum 1,1,1-TCA concentration is 260 µg/L, detected in 1991 in well W-834-S8.
- 1,1,1-TCA concentrations have declined to below the reporting limit range of 0.5 to 2.5 µg/L in all leachfield area Tps-$Tnsc_2$ HSU wells during 2021.
- The historical maximum CFORM concentration is 6.1 µg/L, detected in 1993 in well W-834-S8.
- CFORM concentrations have declined to a current 2021 maximum of 2 µg/L, detected in February in well W-834-S8.

Similar to results from recent years, concentrations of other VOCs in leachfield area Tps-$Tnsc_2$ HSU wells (including *trans*-1,2-DCE; 1,1-DCE; 1,1-DCA; 1,2-DCA; 1,1,2-TCA; Freon 11; Freon 113; CTET; and vinyl chloride) either did not exceed reporting limits or were below applicable MCL cleanup standards.

Distal Area

VOC concentrations and distribution in groundwater in the Tpsg, Tps-$Tnsc_2$, and $Tnbs_1$ HSUs in the Building 834 distal area are discussed below.

Tpsg HSU

Since monitoring began in 1989, the Tpsg HSU in the distal area has continued to exhibit declining VOC concentrations. There are 23 monitor wells completed in this HSU. In the T2 area, the Tpsg HSU has been the target of a long-term enhanced *in situ* bioremediation treatability study since 2005, as discussed in Section 2.2.3.4 of this report. While TVOC concentration reductions of an order of magnitude have been achieved since the start of the treatability study, elevated VOC concentrations continue to occur in the vicinity of distal area wells W-834-2117, W-834-T2A, W-834-T2B, W-834-T2D, W-834-1825, and W-834-1833.

Concentrations of primary COC VOCs in Tpsg HSU groundwater within the distal area are generally declining:

- The historical maximum TVOC concentration is 86,000 µg/L, detected in 1988 in well W-834-T2A.
- TVOC concentrations have declined to a current 2021 maximum of 6,600 µg/L, detected in September in well W-834-T2B.
- The historical maximum TCE concentration is 86,000 µg/L, detected in 1988 in well W-834-T2A.
- TCE concentrations have declined to a current 2021 maximum of 6,600 µg/L, detected in August in well W-834-T2B.
- The historical maximum *cis*-1,2-DCE concentration is 6,200 µg/L, detected in 2008 in well W-834-T2.
- *cis*-1,2-DCE concentrations have declined to a current 2021 maximum of 230 µg/L, detected in February in well W-834-1833.
- The historical maximum PCE concentration is 160 µg/L, detected in 1987 in well W-834-S6.

- PCE concentrations have declined to a 2021 maximum of 25 µg/L, detected in February in well W-834-3302.
- The historical maximum 1,1,1-TCA concentration is 200 µg/L, detected in 1991 in well W-834-T2D.
- 1,1,1-TCA concentrations have declined to below the reporting limit range of 0.5 µg/L to 2.5 in all distal area Tpsg HSU wells during 2021.
- The historical maximum CFORM concentration is 270 µg/L, detected in 1999 in well W-834-M1.
- CFORM concentrations have declined to a current 2021 maximum of 2.3 µg/L, detected in August in well W-834-T2B.

Although not a COC, during the reporting period, vinyl chloride was detected above the reporting limit in two distal area Tpsg HSU wells; in well W-834-T2 at 16 µg/L (August) and 1.5 µg/L (February), and in well W-834-1833 at 2.8 µg/L (September). Similarly, 1,1-DCE was detected above the reporting limit in three distal area Tpsg HSU wells, with well W-834-1833 exceeding the 6 µg/L MCL cleanup standard slightly at 8 µg/L (September). Freon 11, Freon 113, 1,1-DCA, and 1,2-DCA were not detected above their reporting limits in any distal area wells. Other VOCs including *trans*-1,2-DCE, 1,1-DCE, CFORM, CTET, and 1,1,2-TCA were detected slightly above reporting limits, but did not exceed applicable MCL cleanup standards.

Tps-Tnsc$_2$ HSU

The intermediate depth Tps-Tnsc$_2$ HSU is monitored by two wells, W-834-2119 and new well W-834-3706, which yielded a 2021 maximum TVOC concentration of 12,000 µg/L (nearly all TCE, September). The historical maximum concentration is 16,700 µg/L (August 2012). Since August 2012, TVOC concentrations have been stable to generally decreasing. The 2021 maximum concentration of PCE (20 µg/L) was detected in well W-834-3706 (September). The historical maximum PCE concentration was observed in well W-834-2119 at 24 µg/L in 2015. Maximum concentrations of TCE (12,000 µg/L), *cis*-1,2-DCE (37 µg/L), CFORM (3.2 µg/L), 1,1-DCE (2.8 µg/L), Freon 11 (1.6 µg/L), CTET (1.2 µg/L), and *trans*-1,2-DCE (0.7 µg/L) occurred in September in well W-834-2119, while a maximum concentration of 1,1,2-TCA (1.4 µg/L) occurred in October in well W-834-3706. Other VOCs were not detected above their respective reporting limits during 2021. Only TCE, PCE, and *cis*-1,2-DCE exceeded their MCL cleanup standards in 2021.

Tnbs$_1$ HSU

In the distal area, the deep Tnbs$_1$ HSU is monitored by guard wells W-834-T1 and W-834-T3. TCE and other VOCs were not detected in any of the four samples collected from each well during this reporting period and have only been detected three times in these wells: once each in 1986 and 1987 when very low concentrations of TCE (less than 4 µg/L) were detected immediately following well installation and were likely caused by well bore contamination with shallow soil during the drilling of well W-834-T1, and once in 1994 when 1 µg/L was detected in well W-834-T3.

2.2.3.2.2. TBOS/TKEBS Concentrations and Distribution

TBOS/TKEBS is found primarily in the core area, with the highest concentrations observed in the Tpsg HSU. TBOS/TKEBS concentrations in groundwater have decreased from a historical maximum of 7,300,000 µg/L (core area Tpsg HSU monitor well W-834-D3, 1995) to a 2021 maximum of

600 µg/L (same well). Only three of the 29 wells in the Building 834 OU yielded TBOS/TKEBS concentrations above the 10 µg/L reporting limit during 2021, all in the core area Tpsg HSU: 230 µg/L (July) and 28 µg/L (March) in extraction well W-834-D4, the aforementioned 600 µg/L (February) in monitor well W-834-D3, and 34 µg/L (February) in monitor well W-834-J2. Reported TBOS/TKEBS concentrations often differ significantly from one sampling event to the next. Although several attempts have been made to identify and measure TBOS/TKEBS as a floating product, it was last visually observed in some core area wells in the mid-1990s. Wells where TBOS/TKEBS is a co-contaminant with TCE generally exhibit the highest concentrations of microbial degradation products, such as *cis*-1,2 DCE and vinyl chloride, accumulating under anaerobic conditions when the SVE system is not operational.

During 2021, TBOS/TKEBS were not detected in core area Tps-Tnsc$_2$ wells, or any leachfield and distal area wells.

Because TBOS/TKEBS concentrations in Tpsg HSU wells in the leachfield and distal areas have historically been low or below reporting limits, sampling for TBOS/TKEBS in the leachfield and distal areas is performed biennially, with approximately half the wells sampled during even-numbered years and half sampled during odd-numbered years. During 2021, four leachfield area Tpsg HSU wells and five distal area Tpsg HSU wells were sampled for TBOS/TKEBS analysis; there were no detections above the reporting limit of 10 µg/L.

The concentrations and extent of TBOS/TKEBS in groundwater are greater in the Tpsg HSU than in the underlying Tps-Tnsc$_2$ HSU, because these compounds are light non-aqueous-phase liquids. The historical maximum TBOS/TKEBS concentration in the underlying Tps-Tnsc$_2$ HSU is 110 µg/L (W-834-U1, 2009). During this reporting period, concentrations of TBOS/TKEBS in the Tps-Tnsc$_2$ HSU were below reporting limits in samples collected in February and March from three core area wells and one leachfield area well, and in September from one distal area well. TBOS/TKEBS concentrations also remained below the reporting limit in February and September samples from deep Tnbs$_1$ HSU guard wells W-834-T1 and W-834-T3.

2.2.3.2.3. Nitrate Concentrations and Distribution

During 2021, nitrate concentrations in Tpsg HSU groundwater exceeded the 45 mg/L MCL cleanup standard in the Building 834 core, leachfield, and distal areas, and ranged from below the 0.5 mg/L reporting limit to a maximum concentration of 430 mg/L (distal area monitor well W-834-T2B, February). Specifically, nitrate exceeded the 45 mg/L MCL cleanup standard in:

- Six core area wells at concentrations ranging from 51 to 180 mg/L;
- Three leachfield area wells at concentrations ranging from 98 to 160 mg/L; and
- Nine distal area wells at concentrations ranging from 58 to 430 mg/L.

These concentrations were within historical ranges observed in these wells since 2006. In the core area, nitrate concentrations in the Tpsg HSU varied spatially and temporally. This may be due to denitrification associated with the ongoing *in situ* biodegradation of VOCs. Nitrate concentrations in all other Tpsg HSU wells were below the 45 mg/L MCL cleanup standard or did not exceed the typical reporting limit of 0.5 mg/L. Although both natural (soil) and anthropogenic sources contribute to the nitrate in the perched groundwater, the anthropogenic sources are more significant.

In the underlying Tps-Tnsc$_2$ HSU, 2021 nitrate concentrations in groundwater exceeded the 45 mg/L MCL cleanup standard in:

- Two core area well (W-834-3302, 100 mg/L, February; and W-834-1711, 82 mg/L, February);
- Two leachfield area wells (W-834-S8, 130 mg/L, February; and W-834-S9, 85 mg/L, February);
- Two distal area well (W-834-2119, 98 mg/L, February, and W-834-3706, 110 mg/L, October); and
- One well south of the distal area (W-834-T5, 82 mg/L, February).

These nitrate concentrations were within the historical ranges observed in these wells since 2006. During the reporting period, nitrate concentrations in all other Tps-Tnsc$_2$ HSU wells were below the 45 mg/L MCL cleanup standard.

Nitrate concentrations in groundwater have decreased from a historical maximum of 749 mg/L (monitor well W-834-K1A, 2000) to a current 2021 maximum of 430 mg/L (W-834-T2B, February). However, the persistence of elevated nitrate indicates that an ongoing source of nitrate to groundwater exists, likely a combination of both natural and anthropogenic sources, including the proximal leachfield septic system. Nitrate did not exceed the reporting limit in samples collected from deep Tnbs$_1$ HSU guard wells W-834-T1 and W-834-T3 in February and September.

2.2.3.2.4. Other Contaminant Concentrations and Distribution

The extent of diesel in groundwater in the Building 834 area is limited to the vicinity of a former underground storage tank located beneath the paved portion of the core area. Diesel concentrations have decreased from a historical maximum of 3,900,000 µg/L in well W-834-S8 (2004) to a 2021 maximum of 2,000 µg/L (well W-834-2001, March). A July sample from well W-834-2001 did not yield diesel concentrations above the laboratory reporting limit of 200 µg/L. Two other core area wells, W-834-A1 and W-834-U1, sampled in February, did not yield diesel concentrations above the reporting limit. Diesel concentrations in groundwater tend to vary from one sampling event to the next, likely due to varying amounts of free-phase product in the subsurface and fluctuating groundwater levels. No floating product was observed in groundwater during 2021.

Two wells in the Building 834 OU, W-834-2118 and W-834-3706, were sampled for perchlorate during 2021. Perchlorate concentrations have decreased from a historical maximum of 11 µg/L (well W-834-2118, 2005) to a 2021 maximum of 4.2 µg/L in well W-834-2118 (February), which is below the 6 µg/L MCL cleanup standard. A September sample from W-834-3706 yielded 2 µg/L of perchlorate.

2.2.3.3. Building 834 OU Remediation Optimization Evaluation

Historically, substantially more VOC mass has been removed by SVE than by groundwater extraction. During 2021, this disparity continued with the operation of the SVTS throughout the period while the GWTS was operated for approximately 2,800 hours (32%) of the entire year and for approximately 2,283 hours (52%) of the second semester of 2021. During 2021, 5,501 g of VOCs were removed from the subsurface, mostly by SVE.

During 2021, the SVTS treated approximately 5,329 g of VOCs or 97% of the total VOC mass removed from the vapor phase. Conversely, the GWTS was operated for only a portion of the year due a faulty influent tank transfer pump and wintertime freeze protection periods at the beginning and end of the year, removing approximately 172 g of VOCs during 2021.

During 2021, the total nitrate mass removed was 19 kg and the TBOS/TKEBS mass removed was 0.68 g. Table Summ-1 lists the mass removed by each treatment facility during the entire year of 2021.

Core Area

The Tpsg HSU extraction wellfield within the core area is expected to continue to adequately capture the highest VOC concentrations in groundwater when full and normal operations resume, as planned for 2022. During the reporting period, no modifications were made to the core area extraction wellfield. VOC concentrations in core area monitor wells have been and will continue to be closely monitored to evaluate the performance of active dual extraction, in combination with intrinsic biodegradation during shutdown periods of the SVE system, when the subsurface becomes oxygen-depleted and reducing.

Active groundwater extraction, SVE, and biodegradation have reduced TVOC concentrations in groundwater in the Tpsg HSU core from a historical maximum of 1,100,000 µg/L (well W-834-D5, 1988) to a 2021 maximum of 8,500 µg/L (well W-834-D5, March). During the reporting period, the highest concentrations of TCE were detected in well W-834-D4 at 6,200 µg/L (October) and of *cis*-1,2-DCE in well W-834-D5 at 6,400 µg/L (March). Maximum concentrations of vinyl chloride in 2021 included 170 µg/L in monitor well W-834-D5 (March), 63 µg/L in extraction well W-834-B3 (July), and 57 µg/L in extraction well W-834-D3 (February).

TCE biodegradation continues locally within the core area, where a significant mass of TBOS/TKEBS has historically been present. During 2021, TBOS/TKEBs was detected in three core area wells at concentrations of 600 µg/L, 234 µg/L, and 34 µg/L, in wells W-834-D4, W-834-D3, and W-834-J2, respectively; however, it was not detected above reporting limits in samples collected from 11 other core area Tpsg HSU wells (or any other Building 834 OU wells).

During 2021, nitrate concentrations continued to show declining trends in Building 834 OU wells. Nitrate was detected in six core area wells (W-834-C4, W-834-D7, W-834-D12, W-834-J1, W-834-J2, and W-834-3302), at concentrations ranging from 51 to 180 mg/L, similar to concentrations detected in 2020.

VOC concentrations in Tpsg HSU monitor wells W-834-B4 and W-834-C5 are being monitored during the current five-year review period to verify whether long-term decreasing concentration trends continue in these wells. As was the case in 2020, attempts to sample these wells during the first semester of 2021 were unsuccessful because the wells were dry and during the second semester, because of reductions in field staff due to COVID-19. TVOC concentrations in well W-834-B4 decreased from 9,500 µg/L in 2011 to 4,900 µg/L by the first semester of 2019, then increased to 8,400 µg/L in the second semester of 2019, when it was last sampled. Although TVOC concentrations in well W-834-C5 tend to fluctuate with higher concentrations in summer months and lower concentrations in winter months, concentrations have been declining overall since 2012. TVOC concentrations in well W-834-C5 decreased from 65,200 µg/L in July 2012 to 10,300 µg/L in the first semester of 2020. The well was not sampled during the second semester of 2020 or in 2021 due to insufficient water. However, if significant increasing VOC trends are observed during the current

five-year review period, installation of dual extraction wells in the vicinity of wells W-834-B4 and W-834-C5, or *in situ* bioremediation may be considered.

The highest VOC concentrations in the Building 834 OU and at Site 300 have been detected in the Tps-Tnsc$_2$ HSU. TVOC concentrations have decreased from a historical maximum of 298,000 µg/L (2012) to a 2021 maximum of 187,000 µg/L, both in Tps-Tnsc$_2$ HSU monitor well W-834-A1. In 2017, a well planned for dual extraction (W-834-3301) was drilled and screened in this HSU near existing well W-834-A1 to test the feasibility of extracting VOC-bearing groundwater and soil vapor from this low-permeability perching horizon. Due to limited water, this well was sampled for the first time in February 2018, yielding 2,600 µg/L of TVOCs (mostly TCE). Since then, concentrations have been gradually decreasing to 1,100 µg/L (March 2020), 1,000 µg/L (September 2020), and 400 µg/L (February 2021).

Leachfield Area

In the leachfield area, when operating, the extraction wellfield has captured portions of the VOC plume in Tpsg HSU groundwater. However, the areas with the highest VOC concentrations, in the vicinity of monitor well W-834-2113, were not fully captured. In response, monitor well W-834-2113 was converted to a dual extraction well and connected to the Building 834 treatment system in August 2017.

The underlying Tps-Tnsc$_2$ HSU, monitored by two wells, W-834-S8 and W-834-S9, exhibits VOC concentrations significantly lower than in the overlying Tpsg HSU. TVOC concentrations in well W-834-S8 decreased from 5,200 µg/L in 2016 to 610 µg/L in 2017, but rebounded to 3,100 µg/L in February 2021. Similar concentrations were observed in well W-834-S9. TVOC concentrations in that well decreased from 4,600 µg/L in 2016 to 800 µg/L in 2017, but rebounded to 2,800 µg/L in September 2021. TVOC concentrations in both wells generally appear to exhibit an inverse correlation with water-level fluctuations (i.e., when water levels rise, concentrations decline). TVOC data will continue to be reviewed to determine the long-term trend of these fluctuations. VOCs concentrations in groundwater are expected to continue to generally decrease as remediation progresses.

Concentrations of TBOS/TKEBS in both leachfield Tps-Tnsc$_2$ HSU wells have remained below the 10 µg/L reporting limit and nitrate remained above the 45 mg/L MCL cleanup standard during 2021. The deep regional Lower Tnbs$_1$ HSU aquifer continues to be free of contaminants, as demonstrated by quarterly analyses of groundwater from guard wells W-834-T1 and W-834-T3.

Distal Area

Since 2005, the distal area has been the target of a long-term enhanced *in situ* bioremediation treatability study, which is described in greater detail in the section below.

Per the recommendations presented in the Fourth Five-Year Review for the Building 834 Operable Unit (Buscheck et al., 2017b), DOE/LLNL recommended installing a new Tps-Tnsc$_2$ HSU dual extraction well in the T2 portion of the distal area near existing monitor well W-834-2119, because TVOC and nitrate concentrations had been increasing in W-834-2119 since monitoring began in 2005. TVOCs in this well reached a historical maximum of 16,700 µg/L in 2012. Since then, VOC concentrations in well W-834-2119 have been stable to slightly decreasing. In 2017, to satisfy the recommendation of the five-year review, W-834-3302 was drilled with the plan to complete it as a dual extraction well in the Tps-Tnsc$_2$ HSU. However, drilling issues resulted in well W-834-3302 being completed as a two-inch diameter monitor well screened from 30 to 40 ft below ground surface (bgs)

in the shallower Tpsg HSU instead of the Tps-Tnsc$_2$ HSU. To fulfill the five-year review recommendation, well W-834-3706 was successfully installed as a replacement dual extraction well using roto-sonic drilling in May 2021. This well was sampled for the first time during the second semester of 2021. The location of this well is shown on Figure 2.2-1 and the well specifications are listed in Table 2.1.

2.2.3.4. T2 Treatability Study

Since 2005, the distal T2 area has been the target of a long-term enhanced *in situ* bioremediation treatability study in the Tpsg HSU, including biostimulation using sodium lactate (April 2007 to December 2008) and bioaugmentation using KB-1™ (August 2008), a consortium of dechlorinating bacteria containing *Dhc*. This pilot-scale treatability study has included ongoing post-treatment monitoring to determine if VOC concentrations have rebounded since the suspension of biostimulation (January 2009 to present).

The primary objective of this treatability study is to assess the performance of enhanced *in situ* bioremediation of TCE at concentrations greater than 10,000 µg/L in a water-bearing zone typical of TCE contaminant source areas at Site 300. Based on the successful implementation of the treatability study, a Draft Final Phase 2 Pilot Study Work Plan for Enhanced *in situ* Bioremediation at Building 834 was submitted for regulatory review in November 2015 (LLNL, 2015). Regulatory approval of this work plan was received in September 2016. Ethyl lactate would replace sodium lactate as the preferred biostimulation agent for this enhanced *in situ* biotreatability study because it is a more effective electron donor, and it does not add sodium to the groundwater. Water levels declined in several of the T2 area wells in recent years due to regional drought conditions and the ongoing upgradient dual extraction operations. Thus, sufficient groundwater for the implementation of the proposed small-scale recirculation cell has not been available. Additional details regarding the treatability study are presented in Appendix A of the Fourth Five-Year Review for the Building 834 Operable Unit (Buscheck et al., 2017b), and recent VOC, nitrate, and ORP data are summarized below. Wells were not sampled for light hydrocarbons (i.e., dissolved gases ethene, ethane, and methane) and volatile fatty acids in 2021.

The T2 test area includes a treatment zone encompassing electron donor injection well W-834-1824, KB-1™ bioaugmentation well W-834-1825, key performance monitor wells W-834-T2, W-834-T2A, W-834-T2D, and W-834-1833, upgradient compliance monitor well W-834-2117, and downgradient compliance monitor well W-834-2118.

Well W-834-T2

Following the sodium lactate injections into well W-834-1824 in April 2007 and bioaugmentation with KB-1™ into well W-834-1825 in August 2008, TVOC concentrations in well W-834-T2 decreased from a baseline concentration of 10,000 µg/L in January 2007 to a second semester 2021 maximum of 41 µg/L (August). In August 2021, TCE and *cis*-1,2-DCE occurred at concentrations of 16 µg/L and 8.2 µg/L, respectively, while concentrations of 16 µg/L vinyl chloride confirm that reductive dechlorination is still ongoing in well W-834-T2 and the surrounding subsurface, although sodium lactate injections ceased in December 2008. Depleted nitrate concentrations (less than the 0.5 mg/L reporting limit, February), and an ORP of -58 mV (August) in this well also indicate that conditions are still conducive for reductive dechlorination.

Well W-834-T2A

TVOC concentrations decreased significantly from a baseline concentration of 12,030 µg/L in January 2007 to 3,022 µg/L in August 2021 as a result of *in situ* reductive dechlorination. The second semester 2021 maximum TCE concentration was 3,000 µg/L (August), well below the historical maximum of 86,000 µg/L detected in 1988. February nitrate concentrations of 58 mg/L and an ORP of 92 mV (August) show that subsurface conditions have locally changed from anoxic to aerobic, limiting the process of reductive dechlorination.

Well W-834-1825

The TVOC concentration at well W-834-1825 was 1,817 µg/L in February 2021, comprised of 1,600 µg/L of TCE, 210 µg/L of *cis*-1,2-DCE, 3.7 µg/L of PCE, and 3.1 µg/L of *trans*-1,2-DCE; vinyl chloride was not detected above the 2.5 µg/L reporting limit. The ORP was measured at 125 mV (February), and nitrate concentrations of 12 mg/L (February) indicate that the local subsurface has returned to aerobic conditions.

Well W-834-1833

This performance monitor well has exhibited only limited evidence that it has been significantly impacted by any of the treatability study activities, although the TVOC concentrations in this well declined from a baseline of 13,050 µg/L in January 2007 to 2,832 µg/L by September 2021. In September 2021, a groundwater sample from well W-834-1833 contained TCE at 2,600 µg/L, and *cis*-1,2-DCE and vinyl chloride were measured at 210 µg/L and 2.8 µg/L, respectively. Nitrate concentrations of 38 mg/L (February) indicate that conditions surrounding well W-834-1833 are aerobic, while an ORP measurement of -20 mV (September) suggest more conducive conditions for reductive dechlorination, as also suggested by the detection of vinyl chloride. Subsurface heterogeneity is likely responsible for varying redox conditions and the overall poor historical performance of *in situ* bioremediation at this location.

Well W-834-T2D

TVOC concentrations, primarily TCE, declined from 11,000 µg/L in January 2007 to 3,312 µg/L in February 2021, while *cis*-1,2-DCE was detected at 5.2 µg/L and vinyl chloride was not present above the reporting limit of 2.5 µg/L in well W-834-T2D. This performance monitor well exhibited very little evidence that it had been impacted by any of the bioremediation study activities.

Well W-834-1824

This well served as the injection well for both the tracer and sodium lactate during the treatability study. TVOC concentrations decreased significantly from a baseline concentration of 5,900 µg/L in August 2006 to 1.3 µg/L in September 2021 as a result of *in situ* reductive dechlorination. As of September, TCE was detected at 0.78 µg/L, while *cis*-1,2-DCE and vinyl chloride concentrations were not detected above the 0.5 µg/L reporting limit. Nitrate concentrations did not exceed the 10 mg/L reporting limit (February), while the ORP was a-100 mV (September).

Wells W-834-2117 and W-834-2118

TVOC concentrations in upgradient well W-834-2117 declined from a baseline of 20,200 µg/L in June 2005 to 2,122 µg/L by September 2021. This overall decreasing trend was also observed in performance monitor wells W-834-T2A, W-834-T2D, and W-834-1833. Dissolved TCE concentrations are decreasing over time without any significant reduction attributable to *in situ*

bioremediation. TVOC concentrations in well W-834-2118, located downgradient of the T2 treatment zone, have similarly decreased from 600 µg/L in 2005 to 190 µg/L in February 2021.

Summary

Addition of sodium lactate and *Dhc* microorganisms to the subsurface has established redox conditions that are conducive to complete reductive dechlorination of TCE in the Tpsg HSU. If Phase 2 of the treatability study occurs, performance would be judged primarily on the distribution of ethene beyond its current extent and the overall reduction in TVOC concentrations in the T2 area. During 2022, DOE/LLNL will evaluate whether to commence the next phase of the bioremediation treatability study at T2. DOE/LLNL will also consider expanding dual phase extraction in the T2 area as an alternative to continuing the bioremediation treatability study.

2.2.3.5. Building 834 OU Remedy Performance Issues

During the reporting period, groundwater operations were significantly curtailed due to winter freeze protection followed by treatment facility maintenance operations. Groundwater extraction and treatment were limited to approximately 116 days, while SVE and treatment operations were conducted throughout most of the period. This reduction in extraction and treatment may have temporarily affected the performance of the cleanup remedy for the Building 834 OU.

Full dual extraction operations in the Building 834 core area and leachfield area will resume during 2022 and should continue to be effective in reducing VOC mass and concentration in both groundwater and vapor. The remedy is protective of human health and the environment and is making progress toward cleanup.

Per the recommendations presented in the Fourth Five-Year Review, VOC concentration trends are being monitored in Tps-$Tnsc_2$ HSU wells. Installation of additional extraction wells in this HSU may increase the effectiveness of remediation of VOCs beneath the core area. Additionally, DOE/LLNL will evaluate the feasibility and effectiveness of enhanced *in situ* bioremediation in the core area.

2.3. Pit 6 Landfill (OU 3)

The Pit 6 Landfill covers an area of 2.6 acres at the southern boundary of Site 300. From 1964 to 1973, this landfill was used to bury waste in nine unlined debris trenches and animal pits. The buried waste, which includes shop and laboratory equipment, and biomedical waste, is located on or adjacent to the Corral Hollow-Carnegie Fault. Farther east, the fault trends to the south of two nearby water-supply wells, CARNRW1 and CARNRW2 (approximately 200 and 400 ft north of the fault, respectively). These active water-supply wells, located about 1,000 ft east of the Pit 6 Landfill, provide water for the nearby Carnegie State Vehicular Recreation Area (SVRA) and are monitored on a monthly basis.

The Pit 6 Landfill was capped and closed in 1997 under CERCLA to prevent further leaching of contaminants resulting from percolation of rainwater through the buried waste. The engineered, multi-layer cap is intended to prevent rainwater infiltration into the landfill, mitigate potential damage caused by burrowing animals and vegetation, prevent potential hazards from the collapse of void spaces in the buried waste, and prevent the potential flux of VOC vapors through the soil. Surface water flow

on to the landfill is minimized by a diversion channel on the north side and drainage channels on the east, west, and south sides of the cap.

A map of the Pit 6 Landfill OU showing the locations of monitor and water-supply wells is presented on Figure 2.3-1.

2.3.1 Pit 6 Landfill OU Groundwater and Surface Water Monitoring

The sampling and analysis plan for groundwater and surface water monitoring for the entire year is presented in Appendix C. This table also explains deviations from the sampling plan. Analytical results and groundwater elevation measurements obtained during 2021 are presented in Attachment 1 and Appendix D, respectively. A map of groundwater potentiometric surface contours is shown on Figure 2.3-2.

During the second semester of 2021, groundwater monitoring was conducted in accordance with the CMP monitoring and post-closure requirements with the following exceptions: a total of 29 required analyses were not performed: (1) 25 analyses from five different wells (BC6-13, EP6-08, K6-15, K6-21, and K6-36) were not performed because the wells were dry and (2) four analyses from well K6-27 were not performed because the pump was inoperable. The pump was repaired in November 2020, but became inoperable again and is under repair. Since 2000, there has generally been insufficient water to sample the five dry wells.

2.3.2. Pit 6 Landfill OU Remediation Progress Analysis

This section is organized into three subsections: analysis of contaminant distribution and concentration trends, remediation optimization evaluation, and performance issues.

2.3.2.1. Pit 6 Landfill OU Contaminant Distribution and Concentration

At the Pit 6 Landfill OU, VOCs (CFORM and TCE), perchlorate, and tritium are the primary COCs in groundwater. Nitrate is a secondary COC. These COCs have historically been identified within the Qt-$Tnbs_1$ HSU. The concentrations and activity concentrations of COCs in Pit 6 groundwater have declined significantly from their historical maxima. Primary COC concentrations remained below MCL cleanup standards in 2021, with the exception of a single TCE detection at monitor well EP6-09 (5.8 µg/L, February 2021). Nitrate exceeded the MCL in only two monitor wells (K6-18 and K6-23) in 2021. Minor concentration increases of TCE and other COCs during 2021 are attributed to rising groundwater levels observed in some wells in response to seasonal precipitation resulting in localized vadose zone releases.

The Qt-$Tnbs_1$ HSU is divided into the Qt-$Tnbs_1$ North HSU (portion north of the Corral Hollow-Carnegie Fault Zone) and the Qt-$Tnbs_1$ South HSU (portion within the Corral Hollow-Carnegie Fault Zone) due to the difference in saturated thickness and bedding orientation of bedrock strata on either side of this regional fault. Thus, hydraulic response to pumping from the off-site CARNRW water-supply wells and to seasonal rainfall events is different in the two HSUs. A deeper water-bearing zone ($Tnbs_1$ Deep HSU) occurs beneath a low-permeability confining layer at an approximate depth of 170 ft within the $Tnbs_1$ stratigraphic unit north of the fault zone. Transducers in guard wells K6-34 and W-PIT6-1819 continuously monitor water levels in the Qt-$Tnbs_1$ North HSU. During 2021, water-level data from these wells indicated an ongoing hydraulic response to the daily to weekly pumping of nearby off-site water-supply wells CARNRW1 and CARNRW2. Although the pumping of these nearby water-supply wells is not controlled by DOE/LLNL, timing of pumping can

be inferred from the water-level responses observed in wells W-PIT6-1819 and K6-34. Hydraulic responses in 2021 continue to indicate that the CARNRW wells were pumping at a lower rate than before 2014.

Groundwater levels measured in Qt-Tnbs$_1$ North wells during the second semester of 2021 were approximately one ft lower than those measured during the second semester of 2020. The ongoing decline in the water table north of the Corral Hollow-Carnegie Fault Zone since 2017 is likely due to a combination of (1) continued groundwater extraction from the CARNRW wells and (2) below-average rainfall limiting recharge.

The second semester TVOC isoconcentration contour map with individual VOC concentrations (Figure 2.3-3) and the second semester tritium activity isoconcentration contour map (Figure 2.3-4) are presented for the Qt-Tnbs$_1$ HSU. Because each CMR map is representative of contaminant concentrations during a particular semester, the maximum concentration shown on the CMR map may not match the maximum concentration for 2021 described in the text.

2.3.2.1.1 VOC Concentrations and Distribution

Historically, the primary VOCs of concern in Pit 6 groundwater include TCE and CFORM. Other VOCs detected in groundwater in the past include PCE and *cis*-1,2-DCE. During 2021, VOCs were detected above their respective reporting limits in only two Qt-Tnbs$_1$ North HSU monitor wells: EP6-08 and K6-33. No VOCs were detected above their respective MCL cleanup standards. VOCs did not exceed laboratory reporting limits in guard wells W-PIT6-1819 and K6-34.

Qt-Tnbs$_1$ North HSU

Twelve monitor wells and two guard wells are screened in the Qt-Tnbs$_1$ North HSU at Pit 6. General COC concentration trends in groundwater are as follows.

- The historical maximum TCE concentration is 2.8 µg/L, detected in January 2019 in well EP6-08 immediately east and downgradient of the Pit 6 Landfill. TCE concentrations were historically very low in area wells until 2018 when rising groundwater levels caused increases in TCE concentrations in well EP6-08.
- The 2021 TCE maximum (2.6 µg/L, April 2021) was detected in well EP6-08. TCE concentrations at EP6-08 gradually declined throughout the year to 2.3 µg/L (October 2021). Only one other well screened in the Qt-Tnbs$_1$ North HSU, K6-33, had detectable TCE during 2021 (0.87 µg/L, August 2021).
- The historical maximum CFORM concentration is 4.9 µg/L, detected in water-supply well CARNRW2 in 1990.
- The current 2021 CFORM maximum was detected in well EP6-08 (1.4 µg/L, October 2021). This was the only well screened in the Qt-Tnbs$_1$ North HSU yielding CFORM exceeding the laboratory reporting limit of 0.5 µg/L.

During 2021, PCE was detected in a single monitor well, EP6-08, at 4.6 µg/L (January, August, and October 2021). Well EP6-08 was dry between May 2008 and July 2017. When this well was sampled in April 2008, it yielded a TVOC concentration of 1.8 µg/L, comprised of 1.2 µg/L PCE and 0.56 µg/L TCE. Because the well was dry for nearly ten years, it is likely that the approximate nine ft rise in the water level that occurred from 2017 to 2019 leached residual VOCs from the vadose zone into groundwater. The maximum depth of the bottom of the buried waste in Pit 6, immediately west of

the well, is approximately 12 ft bgs. During 2021, water levels fluctuated between approximately 40 and 44 ft below the bottom of the buried waste in Pit 6 (or approximately 52 to 56 ft bgs). During the 1998 El Niño, water levels in well EP6-08 were approximately 14 to 18 ft higher than current levels. Other wells screened in the Qt-Tnbs$_1$ North HSU showed similar water level rises between 2017 and 2021, but individual VOC concentrations remained below reporting limits.

VOCs were not detected in guard wells W-PIT6-1819 and K6-34.

Qt-Tnbs$_1$ South HSU

Thirteen monitor wells and two guard wells are screened in the Qt-Tnbs$_1$ South HSU. General trends of VOCs in OU 3 Qt-Tnbs$_1$ South HSU groundwater are as follows:

- The historical maximum TCE concentration is 250 µg/L, detected in 1988 in well K6-19.
- TCE concentrations have declined to a current 2021 maximum of 5.8 µg/L, detected in monitor well EP6-09 (February 2021). TCE concentrations in EP6-09 declined to below the 5 µg/L MCL cleanup standard during the year (4.4 µg/L, August 2021). With the exception of a single detection in guard well K6-17 (0.87 µg/L, August 2021), the spatial extent of TCE remained limited to an area immediately south of Pit 6 during 2021.
- The historical maximum CFORM concentration is 14 µg/L, detected in 1994 in well K6-19.
- CFORM concentrations remained below the reporting limit of 0.5 µg/L in all Qt-Tnbs$_1$ South HSU wells in 2021.

During 2021, TCE was detected in groundwater samples from six Pit 6 Landfill Qt-Tnbs$_1$ South HSU monitor wells, EP6-09, K6-16, K6-17, K6-18, K6-19, and K6-23, at concentrations ranging from 0.58 to 5.8 µg/L. TCE was detected at guard well K6-17 in a single sample (0.87 µg/L , August 2021), and was below the reporting limit in March, April, September, and November 2021. Groundwater levels in monitor wells EP6-09, K6-16, and K6-19 exhibited a strong recharge response to above average precipitation during the 2017 and 2019 water years, while water levels remained relatively stable in well K6-18. These water level rises may have leached minor residual vadose zone TCE into the groundwater at well EP6-09, and to a lesser extent, at wells K6-16 and K6-19. Monitor well EP6-09 is located at an approximate midpoint along the southern boundary of Pit 6. Well K6-19 is located at the southeast corner of Pit 6. Wells K6-16 and K6-18 are located approximately 200 ft downgradient and southeast of Pit 6, and K6-17 is approximately 350 ft downgradient and southeast of Pit 6 (Figure 2.3-1).

While no longer a COC, *cis*-1,2-DCE was detected in monitor well K6-01S, located south of the Pit 6 Landfill, at 1.8 µg/L (March 2021) and 2.2 µg/L (August 2021). The limited *cis*-1,2-DCE detections are consistent with historical results, and well below the 6 µg/L MCL cleanup standard. No other VOCs were detected in the Qt-Tnbs$_1$ South HSU during this reporting period.

As previously discussed with the regulatory agencies, TCE concentrations in groundwater at monitor well EP6-09 will continue to be monitored. If TCE concentrations increase significantly above the cleanup standard during the current five-year review period, DOE/LLNL may consider remedial measures, depending on the magnitude of increase and spatial extent of TCE above the cleanup standard.

$Tnbs_1$ Deep HSU

Well K6-26 monitors groundwater in the $Tnbs_1$ Deep HSU within the fault zone. No VOCs were detected in this sole $Tnbs_1$ Deep HSU well during 2021. Historically, VOCs were only detected in this well twice and most recently in 1991 (0.9 µg/L of 1,1,1-TCA).

Water-Supply Wells

During the reporting period, VOCs were not detected in the two active water-supply wells (CARNRW1 and CARNRW2) or the two inactive water-supply wells (CARNRW3 and CARNRW4).

2.3.2.1.2. Tritium Activity Concentrations and Distribution

Tritium has never been detected in Pit 6 Landfill groundwater at activity concentrations exceeding the 20,000 picoCurie per liter (pCi/L) MCL cleanup standard. During 2021, tritium was detected slightly above the 100 pCi/L reporting limit in three monitor wells in the Pit 6 Landfill OU (K6-24 and K6-33, both screened in the Qt-$Tnbs_1$ North HSU; and K6-22, screened in the Qt-$Tnbs_1$ South HSU).

Qt-$Tnbs_1$ North HSU

In the Qt-$Tnbs_1$ North HSU, tritium activity concentrations have decreased from a historical maximum of 2,150 pCi/L (well K6-36, 2000) to a 2021 maximum of 137 ±73.9 pCi/L in well K6-33 (August 2021). In 2020, the maximum activity concentration at Pit 6 of was detected at monitor well K6-36 (400 ±124 pCi/L, January 2020). Well K6-36 was dry and not sampled in 2021. The only other Qt-$Tnbs_1$ North HSU sample containing tritium exceeding the 100 pCi/L reporting limit was 106 ±70.4 pCi/L in monitor well K6-24 (August 2021).

As was the case for the other very low tritium activity concentrations in area groundwater (discussed below), measured tritium activity concentrations were accompanied by relatively large analytical uncertainties and are not indicative of increasing trends in tritium activity concentration or exceedance of background (i.e., less than the 100 pCi/L reporting limit).

At well EP6-07, except for an activity concentration of 255 ±100 pCi/L (January 2016), tritium has not been detected above the 100 pCi/L reporting limit in this well since 2005, including 2021.

Guard well W-PIT6-1819 is located approximately 200 ft west of the CARNRW1 and CARNRW2 water-supply wells and has historically defined the downgradient extent of tritium activity concentrations exceeding 100 pCi/L in Pit 6 groundwater. Since 2007, tritium activity concentrations in W-PIT6-1819 have fluctuated from less than 100 pCi/L to a maximum activity concentration of 295 pCi/L (April 2007) and indicate an overall decreasing trend. From July 2016 to present, with the exception of a single measurement of 110 ±70.5 pCi/L (July 2018), activity concentrations in W-PIT6-1819 have not exceeded the 100 pCi/L reporting limit. In guard well K6-34, tritium has only been detected three times since monitoring began in 2000, with the most recent detection occurring in October 2018 just above the 100 pCi/L reporting limit (107 ±73.9 pCi/L).

Qt-$Tnbs_1$ South HSU

In the Qt-$Tnbs_1$ South HSU, tritium activity concentrations have decreased from a historical maximum of 3,420 pCi/L in 2000 (monitor well BC6-13, which monitors Spring 7) to a single detection of tritium at 100 ±70.8 pCi/L in 2021 (K6-22, March 2021).

$Tnbs_1$ Deep and Tmss HSUs

The historical maximum tritium activity concentration in the $Tnbs_1$ Deep HSU is 1,680 pCi/L (monitor well K6-26, 1999), well below the 20,000 pCi/L MCL cleanup standard. In January 2020,

tritium was detected slightly above the 100 pCi/L reporting limit in Tmss HSU well K6-25 at 116 ±83.9 pCi/L. Since monitoring was initiated in this well in 1995, tritium has only exceeded the reporting limit once, at 215 pCi/L in 2005. Tritium was below the 100 pCi/L reporting limit in well K6-25 throughout 2021. This well will be monitored for any future trends.

Water-Supply Wells

During this reporting period, tritium was not detected above the 100 pCi/L reporting limit in the active CARNRW water-supply wells (CARNRW1 and CARNRW2) and inactive CARNRW water-supply well CARNRW4. At inactive water supply well CARNRW3, there was a single detection of tritium slightly above the reporting limit in the routine sample (124 ±80.7 pCi/L, July 2021). Tritium did not exceed the reporting limit (100 pCi/L) in the duplicate sample. CARNRW3 is sampled on a monthly basis and there were no additional tritium detections throughout 2021. As discussed above, this measured tritium activity concentration was accompanied by a relatively large analytical uncertainty and is not likely indicative of an increasing trend in tritium activity or exceedance of background (less than the 100 pCi/L reporting limit).

Qal-Tts HSU

In July 2015, tritium was detected in well W-33C-01 (187 ±83.5 pCi/L), located approximately 60 ft south of the Site 300 boundary within the Carnegie SVRA and screened in the Qal-Tts stratigraphic unit. Other than the 2015 detection, tritium has not been measured above the reporting limit in well W-33C-01 since monitoring was initiated in 2000.

2.3.2.1.3. Perchlorate Concentrations and Distribution

The historical maximum concentration of perchlorate in a Qt-Tnbs$_1$ North HSU well is 14 µg/L, detected in well K6-35, in 2003. Since 2004, perchlorate has not been detected above the reporting limit (typically 4 µg/L) in any Qt-Tnbs$_1$ North HSU well, including the two guard wells. In 2021, there were no detections of perchlorate in any Pit 6 monitor wells.

Qt-Tnbs$_1$ South HSU

Perchlorate concentrations in Qt-Tnbs$_1$ South HSU wells have decreased from a historical maximum of 65.2 µg/L in well K6-19 (1998) to below reporting limit throughout 2021. The perchlorate reporting limit was typically 4 µg/L during the first semester of 2021 and 2 µg/L during the second semester of 2021.

The 2020 maximum perchlorate concentration of 5.1 µg/L in well K6-18 was a decline from the recent maximum of 11 µg/L in January 2018. Well K6-18 was sampled in 2021 (March) and perchlorate did not exceed the best achievable reporting limit for the sample of 20 µg/L. During 2020, ORP field measurements of -94 mV (January) and -74 mV (September), suggest microbial reduction of perchlorate under anaerobic conditions may have lowered concentrations to below reporting limits. Similar anaerobic subsurface conditions and lowered perchlorate concentrations were observed at this well in 2012 and 2013. ORP measurements increased in 2021 to 52 mV (August 2021). Between 2014 and 2019, perchlorate concentrations ranging from 5.1 to 11 µg/L were accompanied by positive ORP measurements greater than +53 mV, suggesting oxidizing conditions that would not support microbial reduction. Similarly, nitrate concentrations in well K6-18 were very low at 2.1 mg/L and 2.7 mg/L in 2012 and 2013, respectively, increasing to 210 mg/L in 2015, followed by a decline to 83 mg/L (September 2020), and 66 mg/L (August 2021). It is possible that the decreases and increases in the concentrations of perchlorate and nitrate in K6-18 groundwater observed since 2012 resulted from

bacterially-motivated reduction of nitrate and perchlorate, followed by an upgradient influx of oxygen-, perchlorate-, and nitrate-bearing water in 2014 and later. In addition to ORP, dissolved oxygen (DO) will be measured in this well to independently determine whether local bacterially-motivated degradation of perchlorate and nitrate is occurring during periods of lower rainfall.

As previously discussed with the regulatory agencies, the perchlorate trends in wells K6-16, K6-18, and K6-19 will continue to be closely monitored. If elevated concentrations of perchlorate persist, an evaluation will be conducted to better constrain potential sources, including the Building 899 septic system and the influence of local geochemistry.

$Tnbs_1$ Deep and Tmss HSUs

Perchlorate did not exceed the 4 µg/L reporting limit in any $Tnbs_1$ Deep HSU or Tmss HSU wells during 2021.

Water-Supply Wells

During 2021, perchlorate was not detected above the 2 to 4 µg/L reporting limit in the two active CARNRW water-supply wells (CARNRW1 and CARNRW2) or two inactive CARNRW water-supply wells (CARNRW3 and CARNRW4).

2.3.2.1.4. Nitrate Concentrations and Distribution

During 2021, nitrate was detected in groundwater samples collected from wells screened in the Qt-$Tnbs_1$ North and South HSUs.

Qt-$Tnbs_1$ North HSU

In the Qt-$Tnbs_1$ North HSU during 2021, nitrate was detected at a maximum concentration of 14 mg/L in well K6-24 (March 2021), below the 45 mg/L MCL cleanup standard and a decline from the 2020 and 2019 concentrations of 25 and 47 mg/L, respectively, in this well. The 2021 and 2020 nitrate concentration data for this well were marked as suspect. Future analyses will better confirm nitrate concentrations in this well. Additionally, nitrate was detected in four other wells in the Qt-$Tnbs_1$ North HSU during this reporting period at concentrations ranging from 1.4 to 5.6 mg/L. The historical maximum nitrate concentration in Qt-$Tnbs_1$ North HSU groundwater is 63 mg/L, detected in well K6-24 in 2011.

From 1998-2006, nitrate concentrations in well K6-24 remained low (less than 2 mg/L). In April 2011, the nitrate concentration in this well increased to 63 mg/L. The well went dry during the second semester of 2011. By January 2017, water levels had recovered sufficiently, and the sample collected at that time contained 46 mg/L of nitrate. The 2018 and 2019 January samples contained 46 mg/L and 47 mg/L of nitrate, respectively, declining to 25 mg/L in January 2020, and to 14 mg/L in March 2021. Nearby well W-PIT6-2817 yielded only 2.2 mg/L of nitrate (March 2021).

During 2021, nitrate was detected at 1.4 mg/L in March 2021 at guard well W-PIT6-1819. Nitrate concentrations were below the 0.5 mg/L reporting limit in W-PIT6-1819 throughout 2020. After the March detection, nitrate returned to below the reporting limit in August 2021. Historically, nitrate has either not been detected above the 0.5 mg/L reporting limit or been detected at very low concentrations in this well, including the historical maximum of 8.1 mg/L in 2012. Nitrate was not detected above the reporting limit during this reporting period in guard well K6-34, sampled in March and August.

Qt-Tnbs$_1$ South HSU

In the Qt-Tnbs$_1$ South HSU, nitrate was detected during 2021 in six wells, at concentrations ranging from 3 to 69 mg/L, exceeding the MCL cleanup standard of 45 mg/L in two wells, K6-18 and K6-23. The historical maximum nitrate concentration for this HSU is a 2019 detection of 250 mg/L in well K6-23. Well K6-23 is located in close proximity to the Building 899 septic system, which is the likely source of the nitrate at this location (Dibley et al., 2013).

Well K6-18, located approximately 240 ft west-northwest and upgradient of well K6-23 and the Building 899 septic system, exceeded the MCL cleanup standard prior to 2014 only in 1998 (an El Niño year) and in 2009. Nitrate concentrations increased significantly from 16 mg/L (January 2014) to 210 mg/L (January 2015) but declined to 83 mg/L in 2020 and to 66 mg/L (August) in 2021. Well K6-16, located in the vicinity of K6-18, which exhibited a modest increase in nitrate from 10 mg/L (2016) to 44 mg/L (January 2020), while groundwater levels remained relatively stable, showed a concentration decline during the reporting period to 30 mg/L (March 2021). As stated above with respect to perchlorate, variations in nitrate and perchlorate concentrations observed at this well may correlate with bacterially-motivated redox changes in the groundwater (i.e., nitrate concentrations are low when ORP data indicate anoxic or reducing geochemical conditions).

Well K6-19, located at the southeast corner of the Pit 6 Landfill and approximately 400 ft west-northwest and upgradient of K6-23 and the Building 899 septic system, yielded a nitrate concentration of 5.3 mg/L (February 2021). This was a significant decline from the 82 mg/L detection in January 2017. The January 2017 nitrate concentration was the only detection above the MCL cleanup standard since the well was installed in 1988 and the first above the nitrate reporting limit since 2002. The water level in well K6-19 rose approximately 1.5 ft from the first semester of 2016 to the first semester of 2017, then remained relatively stable through 2021. The rise may have caused the leaching of some available vadose zone nitrate into the groundwater.

In well K6-16, located approximately 80 ft south of K6-18, and 225 ft west and upgradient of the Building 899 septic system, nitrate concentrations declined to 30 mg/L (March 2021). Since January 2016, nitrate concentrations in this well had steadily risen from 10 mg/L to 49 mg/L (January 2019), exceeding the MCL for the first time before declining to 44 mg/L (January 2020). Water levels in well K6-16 rose approximately 1.2 ft from January 2015 to January 2017, but have remained relatively stable since then. Nitrate was not detected at concentrations above the MCL cleanup standard in groundwater samples from any other wells completed in the Qt-Tnbs$_1$ South HSU, including guard wells K6-17 and K6-22.

All wells exhibiting recent nitrate concentrations in excess of the MCL cleanup standard will continue to be closely monitored to assess whether the elevated nitrate concentrations persist and to evaluate the potential sources of nitrate, including the vadose zone beneath the Pit 6 Landfill and the Building 899 septic system.

Tnbs$_1$ Deep HSU

Including 2021, nitrate has never been detected above its 45 mg/L MCL cleanup standard in groundwater samples from the Tnbs$_1$ Deep HSU or Tmss HSU.

Water-Supply Wells

During the reporting period, maximum nitrate concentrations of 1.5 mg/L (October 2021) were detected in active water supply well CARNRW2. Nitrate was not detected above the reporting limit of

0.5 mg/L in active water-supply well CARNRW1, or above reporting limits of 0.5 mg/L to 1 mg/L in inactive water-supply wells CARNRW3 and CARNRW4. All nitrate concentrations were well below the 45 mg/L MCL cleanup standard in the water-supply wells.

2.3.2.2. Pit 6 Landfill OU Remediation Optimization Evaluation

The remedy for tritium and VOCs in groundwater at the Pit 6 Landfill is monitored natural attenuation (MNA). Groundwater levels and contaminants are monitored on a regular basis to evaluate the efficacy of natural attenuation in reducing contaminant concentrations and to detect any new chemical releases from the landfill. In general, concentrations of the primary groundwater COCs (CFORM, TCE, perchlorate, and tritium) at the Pit 6 Landfill OU continue to decline. During 2021, groundwater levels beneath the landfill ranged from approximately 30 ft (in wells located within the Corral Hollow-Carnegie Fault Zone) to 43 ft (in wells located north of the Corral-Hollow-Carnegie Fault Zone) below the buried waste.

Overall, VOC concentrations in groundwater near Pit 6 continue to exhibit decreasing trends. Except for very low concentrations detected in a single well adjacent to the landfill (EP6-08) and one well cross-gradient and screened in the Qal-Tts HSU, CFORM was below the reporting limit in all Pit 6 Landfill OU wells. Although no longer a COC, *cis*-1,2-DCE was detected once in a single well (K6-01S) and has remained below the 6 µg/L MCL cleanup standard since 1993. During 2021, only well, EP6-09 yielded a TCE concentration (5.8 µg/L, February 2021) above the MCL cleanup standard (5 µg/L), before declining to below the MCL cleanup standard during the review period (4.4 µg/L, August 2021). As discussed previously, if TCE concentrations increase significantly above the cleanup standard in well EP6-09, remedial measures may be considered depending on the magnitude of increase and spatial extent of TCE. Recently rising groundwater may have leached some available vadose zone TCE near well EP6-09 into the groundwater.

Tritium activity concentrations in groundwater continue to remain far below the 20,000 pCi/L MCL cleanup standard. During 2021, tritium activity concentrations remained low, slightly exceeding the 100 pCi/L reporting limit in only four wells: K6-22, K6-24, K6-33, and CARNRW3. The very low, intermittently detected tritium activity concentrations in these wells appear to be the result of the relatively high analytical uncertainty for tritium in these samples (near the detection limit) and are not indicative of increasing tritium trends in groundwater. Accordingly, these results confirm that the MNA remedy for tritium at the Pit 6 Landfill OU continues to be effective.

Perchlorate concentrations in OU 3 groundwater have decreased from a maximum of 65 µg/L in well K6-19 (following the 1998 El Niño) to below the reporting limit during 2021. Well K6-18 had shown a consistent decreasing perchlorate trend between 1999 and 2013, after which concentrations increased slightly. The provenance of perchlorate at K6-18, and recently in K6-19, is not known, although the water level rise in well K6-19 since the first semester of 2016 may have leached available vadose zone perchlorate into the groundwater. The perchlorate concentration of 4.3 µg/L in January 2020 in well K6-16 barely exceeded the reporting limit of 4 µg/L and represents the first perchlorate detection in this well since 2000. Concentrations subsequently declined to below the 4 µg/L reporting limit (March 2021). As discussed previously, if elevated local perchlorate concentrations persist, an evaluation will be conducted to determine whether these concentrations are related to the Building 899 septic system or other sources, or correlate with temporal variations in bacterially-motivated breakdown of pre-existing perchlorate. Except for these wells, since March 2009, perchlorate

concentrations have remained below the reporting limit and the 6 µg/L MCL cleanup standard in all other Pit 6 Landfill OU wells.

Nitrate continues to be consistently detected in well K6-23 above its 45 mg/L MCL cleanup standard. As stated above, well K6-23 is located near the Building 899 septic system, the likely source of nitrate at this location. The source of recent nitrate concentrations in well K6-18 above the cleanup standard is not known. Possible causes include the Building 899 septic system, changes in local pre-existing nitrate biodegradation, or rising water levels (encountering vadose zone nitrate) caused by recent rainfall recharge during the winter seasons since 2016. From 2016 through 2019, nitrate was detected slightly above the 45 mg/L MCL cleanup standard in Qt-$Tnbs_1$ South HSU well K6-24, declining to 14 mg/L during 2021.

2.3.2.3. Pit 6 Landfill OU Performance Issues

Currently, the temporal and spatial extent of groundwater in excess of MCL cleanup standards at the Pit 6 Landfill OU is very limited. Based on the preceding discussion, the remedy continues to be effective and protective of human health and the environment while it progresses toward cleanup.

2.4. High Explosives Process Area (OU 4)

The HEPA has been used since the 1950s for the chemical formulation, mechanical pressing, and machining of high explosives (HE) compounds into shaped detonation charges. Surface spills from 1958 to 1986 resulted in the release of contaminants at the former Building 815 steam plant. Subsurface contamination is also attributed to HE wastewater discharges into former unlined rinse water lagoons. Another minor source of contamination in groundwater was leaking contaminated waste stored at the former Building 829 waste accumulation area (WAA) located near Building 829.

Four GWTSs operate in the HEPA: Building 815-SRC, Building 815-Proximal (815-PRX), Building 815-Distal Site Boundary (815-DSB), and Building 817-Proximal (817-PRX). Two other GWTSs, Building 817-Source (817-SRC) and Building 829-Source (829-SRC), were converted to GWESs. Water from both systems is collected in portable tanks and transported to the 815-SRC or the 815-PRX GWTS for treatment. A map of the HEPA OU showing the locations of wells and treatment facilities is presented on Figure 2.4-1.

The 815-SRC GWTS began operation in September 2000, removing VOCs (primarily TCE), HE compounds (RDX and High-Melting Explosive [HMX]), and perchlorate from groundwater. System upgrades were implemented during the first semester of 2017. During the second semester of 2021, groundwater was extracted from wells W-815-02, W-815-04, and W-815-2803 at a combined flow rate of approximately 1.2 gpm. The current GWTS configuration includes a Cuno® filter to remove particulates, two ion-exchange resin columns connected in series for perchlorate removal, and three aqueous-phase GAC vessels (also connected in series) for VOC and HE compound removal. The treated effluent is injected into well W-815-1918 where *in situ* denitrification within the $Tnbs_2$ HSU reduces the nitrate to nitrogen. Naturally motivated *in situ* denitrification is the process by which indigenous microbes in an aquifer oxidize any available electron donor (typically organic carbon, but usually pyrite at Site 300) in the aquifer to the condition where all oxygen in the aquifer has been utilized. At that point, bacterially-motivated anaerobic oxidation of the organic carbon occurs in concert with the step-wise reduction of nitrate to nitrogen gas (NO_3 to NO_2 to NO to N_2O to N_2), in which the nitrogen oxides serve as terminal electron acceptors in the absence of oxygen.

The 815-PRX GWTS began operation in October 2002, initially removing only TCE and perchlorate from groundwater. However, beginning in 2011, the HE compound RDX began showing up in samples collected from the extraction wells. During the second semester of 2021, groundwater was extracted from well W-818-09 at a flow rate of approximately 0.9 gpm; well W-818-08 was non-operational for all of the reporting period until December, when groundwater extraction resumed at a flow rate of approximately 0.4 gpm. The well was non-operational because of a pump replacement that took longer than anticipated due to supply chain issues. The current GWTS configuration includes a Cuno® filter to remove particulates, two ion-exchange resin columns connected in series for perchlorate removal, and three aqueous-phase GAC vessels (also connected in series) for TCE and RDX removal. The treated effluent is injected into well W-815-2134 to undergo *in situ* denitrification in the $Tnbs_2$ HSU.

The 815-DSB GWTS began operation in September 1999, removing low concentrations (less than 10 µg/L) of TCE from groundwater extracted near the Site 300 southern boundary. During the second semester of 2021, groundwater was extracted from wells W-35C-04, W-6ER, and W-815-2608 at a combined flow rate of approximately 2.1 gpm. The current GWTS configuration includes a Cuno® filter to remove particulates and three aqueous-phase GAC vessels connected in series for TCE removal. The treated effluent is discharged to an infiltration trench.

The 817-SRC GWTS began operation in September 2003, removing HE compounds (RDX and HMX) and perchlorate from groundwater. This system was converted to an extraction and collection system in April 2017. Groundwater collected is transferred to the 815-SRC or 815-PRX GWTS for treatment. The single extraction well, W-817-01, extracts groundwater from a very low yield portion of the $Tnbs_2$ aquifer. The 817-SRC extraction system operated for 5,040 hours during the second semester of 2021 using solar power and extracted a total of 982 gal.

The 817-PRX GWTS began operation in September 2005, removing VOCs, RDX, and perchlorate from groundwater. During the second semester of 2021, groundwater was extracted from well W-817-03 at a flow rate of approximately 1.2 gpm; well W-817-2318 was non-operational for the entirety of the reporting period. The well was non-operational because of a declining water level and low recharge at this location leading to the well having insufficient water for pumping. The current GWTS configuration includes a Cuno® filter to remove particulates, two ion-exchange resin columns connected in series for perchlorate removal, and three aqueous-phase GAC vessels (also connected in series) for removal of VOCs and HE compounds. Treated groundwater containing nitrate is injected into upgradient injection wells W-817-2109 and W-817-02 to undergo *in situ* denitrification in the $Tnbs_2$ HSU.

The 829-SRC GWES began operation in August 2005, removing VOCs, nitrate, and perchlorate from groundwater. Currently, groundwater is extracted from well W-829-06 at a flow rate of approximately 60 gal per month and transported for treatment to the 815-SRC or 815-PRX GWTS. A total of 375 gal were extracted during this reporting period.

2.4.1. HEPA OU Groundwater Extraction and Treatment System Operations and Monitoring

2.4.1.1. HEPA OU Compliance Summary

The 815-SRC, 815-PRX, 815-DSB, and 817-PRX GWTSs operated in compliance with the RWQCB substantive requirements for wastewater discharge throughout this reporting period. Several leaks occurred during the second semester at 815-DSB and 815-SRC. The volumes and contaminant masses for each release were reported to appropriate management and technical personnel. The 817-SRC and 829-SRC GWESs do not have any regulatory discharge requirements.

The HEPA OU treatment facility sampling and analysis plan complies with the monitoring requirements in the CMP/CP; the sampling and analysis plan for the first semester of 2022 is presented in Appendix B. All required influent and effluent samples were collected according to the plans that were provided in the previous two CMRs.

2.4.1.2. HEPA Operations and Maintenance Issues

Information concerning HEPA facilities operations and maintenance issues is presented in Table 2.5.

2.4.1.3. HEPA OU Facility Performance Assessment

The monthly groundwater discharge volumes, extraction flow volumes, and operational hours during the second semester of 2021 are summarized in Table 2.2. The total volume of groundwater extracted and treated, and the total contaminant mass removed during the reporting period are presented in Table Summ-1. The historical total volumes of groundwater treated and discharged, and the total contaminant mass removed are summarized in Table Summ-2. Analytical results for influent and effluent samples collected during the second semester of 2021 are presented in Table 2.4. The pH measurements are presented in Appendix A.

2.4.1.4. HEPA OU Treatment Facility and Extraction Wellfield Modifications

No changes were made to any of the HEPA GWTSs or wellfields during the second semester of 2021.

2.4.2. HEPA OU Groundwater and Surface Water Monitoring

Figure 2.4-1 shows the location of wells in the HEPA OU. The sampling and analysis plan for groundwater and surface water monitoring for the full year is presented in Appendix C. This table also explains deviations from the sampling plan and indicates any additions made to the CMP.

During the second semester of 2021, groundwater monitoring was conducted in accordance with the CMP monitoring requirements with the following exceptions:

- A total of 18 required analyses for 11 different wells and one spring were not performed, because the wells or spring were dry or had insufficient water for sample collection.
- A total of two required analyses were not performed for two wells due to non-operable equipment or restricted access.
- A total of 42 required analyses for 31 different wells were not performed due to pandemic-related limits on personnel availability.

- A total of 12 required analyses for four different wells were not performed due to an analytical laboratory issue.

Analytical results and groundwater elevation measurements obtained during 2021 are presented in Attachment 1 and Appendix D, respectively. Figure 2.4-2 shows groundwater elevations and individual VOC, perchlorate, RDX, and nitrate concentrations for the Tpsg-Tps HSU; Figure 2.4-3 shows the groundwater potentiometric surface map for the $Tnbs_2$ HSU.

2.4.3. HEPA OU Remediation Progress Analysis

This section is organized into four subsections: mass removal, contaminant concentrations and distribution, remediation optimization evaluation, and remedy performance issues.

2.4.3.1. HEPA OU Mass Removal

The monthly groundwater mass removal estimates for the second semester of 2021 are summarized in Table 2.3. The total mass removed during the reporting period and cumulative mass estimates are summarized in Table Summ-1 and Table Summ-2, respectively.

2.4.3.2. HEPA OU Contaminant Concentrations and Distribution

At the HEPA OU, VOCs (mainly TCE) are the primary COCs detected in groundwater; RDX, HMX, 4-amino-2,6-dinitrotoluene (4-ADNT), perchlorate, and nitrate are secondary COCs. Most of the groundwater contamination in the HEPA OU occurs in the $Tnbs_2$ HSU. Some COCs (TCE, RDX, HMX, perchlorate, and nitrate) have also been detected in perched groundwater within the Tpsg-Tps HSU in the vicinity of Buildings 815 and 817. Minor concentrations of VOCs, perchlorate, and nitrate are also present in perched groundwater located in the $Tnsc_{1b}$ HSU beneath the former Building 829 WAA. The WAA is located in the northwest portion of the HEPA. No contamination has been detected in the Upper and Lower $Tnbs_1$ HSUs in the HEPA OU.

Within the HEPA OU: (1) Figure 2.4-2 provides groundwater elevations and individual VOC, perchlorate, RDX and nitrate concentrations for the Tpsg-Tps HSU; (2) Figure 2.4-4 depicts a total VOC isoconcentration contour map for the $Tnbs_2$ HSU; (3) Figure 2.4-5 shows a RDX isoconcentration contour map for the $Tnbs_2$ HSU; (4) Figure 2.4-6 provides a perchlorate isoconcentration contour map for the $Tnbs_2$ HSU; (5) Figure 2.4-7 presents a map showing nitrate concentrations for the $Tnbs_2$ HSU; and (6) Figure 2.4-8 is a Building 829 burn pit site map showing VOC, perchlorate, and nitrate concentrations for the $Tnsc_{1b}$ HSU.

2.4.3.2.1. VOC Concentrations and Distribution

Tpsg-Tps HSU

General trends of VOC concentrations in the Tpsg-Tps HSU:

- The historical maximum TVOC concentration was 450 µg/L in May 1992 in well W-815-01.
- TVOC concentrations decreased to a current maximum of 12 µg/L (entirely TCE) in July 2021 in extraction well W-817-2318.
- VOC concentration trends remained stable or decreased during 2021. The 2021 spatial distribution of TVOC concentrations above the 0.5 µg/L reporting limit remains very similar to the 2020 distribution.

VOCs, primarily TCE, but also 1,1-DCE; 1,2-DCA; *cis*-1,2-DCE; CFORM; and CTET have been detected in the perched water-bearing zones in the Tpsg-Tps HSU. VOCs remained below the 0.5 µg/L reporting limit in Tpsg-Tps monitor well W-35C-05, located near the southern site boundary. The lateral extent of the perched Tpsg-Tps HSU is dependent on seasonal recharge and groundwater extraction rates and varies from year to year. For this reason, some wells screened in the Tpsg-Tps HSU were dry or did not produce sufficient volumes of water for sampling during the reporting period.

During the second semester of 2021, VOCs other than TCE were only detected at concentrations above the 0.5 µg/L reporting limit in monitor wells W-809-01 and W-814-01. Samples collected from monitor well W-809-01 contained 1,1-DCE and CFORM at concentrations well below their MCL cleanup standards. Samples collected from monitor well W-814-01 contained 1,2-DCA, *cis*-1,2-DCE, and CFORM with maximum concentrations of 0.57 µg/L, 0.97 µg/L, and 0.66 µg/L, respectively. The maximum 1,2-DCA concentration was slightly above the 0.5 µg/L MCL cleanup standard. Similar concentrations of the aforementioned VOCs were detected in Tpsg-Tps wells during 2020.

$Tnbs_2$ HSU

General trends of VOC concentrations in the $Tnbs_2$ HSU:

- The historical maximum TVOC concentration was 110 µg/L in May 1992 in extraction well W-818-08.
- TVOC concentrations decreased to a current maximum of 27 µg/L in January 2021 in a sample taken from extraction well W-818-08.
- VOC concentration trends in the $Tnbs_2$ HSU remained stable or decreased slightly in individual wells during the second semester of 2021. The 2021 spatial distributions of TVOC concentrations above the 0.5 µg/L reporting limit, 5 µg/L, and 10 µg/L, remain very similar to their 2020 distributions.

In the $Tnbs_2$ HSU, the highest VOC concentrations are found downgradient of Building 815 in the 815-PRX extraction wellfield. During the reporting period, TCE was detected in the $Tnbs_2$ HSU with concentrations exceeding the 5 µg/L MCL cleanup standard in 19 wells. 1,1-DCE was detected in extraction well W-815-02 at 0.55 µg/L (April), well below the 6 µg/L MCL cleanup standard. *cis*-1,2-DCE was detected in five wells during the reporting period, with a maximum concentration of 0.95 µg/L in groundwater extraction well W-6ER (March). No other VOCs were detected above reporting limits in the $Tnbs_2$ HSU during the second semester of 2021.

VOCs continue to be detected in $Tnbs_2$ HSU groundwater at the southern end of Building 832 Canyon. This contamination probably originates from sources located in both the Building 832 Canyon and HEPA OUs. Since June 2007, when extraction well W-830-2216 began pumping groundwater, TVOC concentrations have decreased from 20 µg/L in May 2007 to a 2021 maximum of 4.7 µg/L (March). A similar decrease in VOC concentrations has been observed in nearby monitor well W-830-13, from 21 µg/L in March 2007 to 4.1 µg/L in February 2021. VOC concentrations in these wells have remained stable since 2019. VOCs were detected in well W-870-02 at a concentration of 0.77 µg/L (September) for the first time since August 2015 when VOCs were detected in this well at a similarly low concentration of 0.93 µg/L. VOCs were not detected above reporting limits in new $Tnbs_2$ monitor well W-830-3409, which was completed in October 2018.

During the reporting period, TCE was detected at concentrations below the 5 µg/L MCL cleanup standard in the samples from $Tnbs_2$ HSU on-site guard wells W-815-2110 and W-815-2111, located

near the Site 300 southern boundary. The maximum TCE concentrations were 1.4 µg/L in a sample taken from W-815-2110 (March), and 0.72 µg/L in the routine sample from W-815-2111 (September). Similar TCE concentrations, well below the 5 µg/L MCL cleanup standard, were detected in these wells in 2020. VOCs were not detected in any other on-site or off-site HEPA $Tnbs_2$ HSU guard wells during the reporting period. Twenty routine and duplicate samples were collected from off-site water-supply well GALLO1 during the second semester of 2021. VOCs were not detected above the 0.5 µg/L reporting limit in any of the GALLO1 samples.

New monitor well W-815-3606 was completed in October of 2020. The well is located in the 815-DSB area, northwest of wells W-6H and W-6J. VOCs were not detected above reporting limits in the routine samples collected in 2021.

$Tnsc_{1b}$ HSU

General trends of VOC concentrations in the $Tnsc_{1b}$ HSU:

- The historical maximum TVOC concentration was 1,013 µg/L in extraction well W-829-06 in 1993.
- TVOCs decreased to a current maximum of 41 µg/L (entirely TCE) in extraction well W-829-06 in April.
- The spatial distribution of TVOC concentrations in the $Tnsc_{1b}$ remained similar to those observed in 2020.

Monitor well W-829-08 had a maximum 2021 TCE concentration of 3.7 µg/L (March); concentrations of TCE have been below the 5 µg/L cleanup standard since 2016. VOCs have never been detected in groundwater from nearby $Tnsc_{1b}$ monitor well W-829-1940, nor in nearby monitor wells screened in the Lower $Tnbs_1$ HSU.

2.4.3.2.2. HE Compound Concentrations and Distribution

Tpsg-Tps HSU

General trends of HE compound concentrations in the Tpsg-Tps HSU:

- The historical maximum RDX concentration was 350 µg/L in well W-815-01 in 1988. This well has not been sampled since 1999, as it has been dry or had insufficient water for sampling.
- HE compounds were not detected in any OU 4 wells screened in the Tpsg-Tps HSU during 2021.
- The spatial distribution of HE compounds in the Tpsg-Tps HSU remained similar to that observed in 2020.

RDX, which was detected in 2018 in monitor well W-817-2318 at 1.2 µg/L and in monitor well W-817-03A at 4.2 µg/L, was not detected in these wells above reporting limits during 2020 or 2021. Some wells in which HE compounds have previously been detected were dry or had insufficient water for sampling during the reporting period.

$Tnbs_2$ HSU

General trends of HE compound concentrations in the $Tnbs_2$ HSU:

- The historical maximum RDX and HMX concentrations were 204 µg/L (1992) and 57 µg/L (1995), respectively, in extraction well W-815-04.

- HE compound concentrations decreased to a current maximum of 42 µg/L (April, well W-817-01) for RDX and 16 µg/L (April, well W-817-01) for HMX.
- Overall, HE compound concentrations remained stable or decreased from 2020 concentrations in the $Tnbs_2$ HSU during 2021; the spatial distribution remained similar to that observed in 2020.

In 2021, RDX was not detected in guard well W-6H, where it had been detected in 2017 for the first time at a concentration of 1.7 µg/L (March), slightly above the 1 µg/L reporting limit. RDX was also not detected in this well during 2019 or 2020. HMX concentrations remain significantly below the regional tapwater screening level of 1,000 µg/L (U.S. EPA, 2017). Concentrations of 4-ADNT in the $Tnbs_2$ HSU have declined from the historical maximum of 24 µg/L (extraction well W-817-01, 1997) to below the reporting limit in 2021. In January 2017, 1,3-dinitrobenzene was detected above the reporting limit in monitor well W-4B for the first time at a concentration of 110 µg/L. This concentration was the site-wide historical maximum for 1,3-dinitrobenzene, previously detected at a maximum of 3.1 µg/L in $Tnsc_2$ HSU monitor well W-6CI in March 2016. However, 1,3-dinitrobenzene was not detected above the reporting limit in a confirmatory sample taken in April 2018, nor in the routine samples taken in 2019, 2020, and 2021. It is likely that the 2017 detection was an anomaly and does not indicate the presence of HE compounds in the vicinity of monitor well W-4B. Nonetheless, monitor well W-4B will continue to be monitored closely.

2.4.3.2.3. Perchlorate Concentrations and Distribution

Tpsg-Tps HSU

General trends of perchlorate concentrations in the Tpsg-Tps HSU:

- The historical maximum perchlorate concentration was 19 µg/L in well W-817-03A in 2000.
- Perchlorate decreased to a current maximum of 11 µg/L in extraction well W-817-2318 in July.
- Perchlorate concentrations and distribution in the Tpsg-Tps HSU in 2021 remained very similar to those observed in 2020.

The only other well in which perchlorate was detected above the 6 µg/L MCL cleanup standard was monitor well W-817-03A (9.6 µg/L, March).

$Tnbs_2$ HSU

General trends of perchlorate concentrations in the $Tnbs_2$ HSU:

- The historical maximum perchlorate concentration was 50 µg/L in extraction well W-817-01 in 1998.
- Perchlorate concentrations decreased to a current maximum of 19 µg/L in the same well in April.
- Perchlorate concentrations decreased or remained stable in the $Tnbs_2$ HSU in 2021 and spatial distribution remained very similar to that observed in 2020.

In the $Tnbs_2$ HSU, groundwater perchlorate concentrations exceeding the 6 µg/L MCL cleanup standard were detected in seven wells during the reporting period. Wells with the highest perchlorate concentrations are located in the vicinity of the 815-SRC GWES, 817-SRC GWES and 817-PRX

GWTS. Perchlorate has not been detected in any of the $Tnbs_2$ HSU guard wells or other monitor wells located near the Site 300 southern boundary to date.

$Tnsc_{1b}$ HSU

General trends of perchlorate concentrations in the $Tnsc_{1b}$ HSU:

- The historical maximum perchlorate concentration was 29 µg/L in extraction well W-829-06 in 2000.
- Perchlorate decreased to a current maximum of 19 µg/L in the same well in April.
- The spatial distribution of perchlorate concentrations in the $Tnsc_{1b}$ remained similar to those observed in 2020.

Extraction well W-829-06 was the only $Tnsc_{1b}$ HSU well with perchlorate concentrations exceeding the 6 µg/L MCL cleanup standard and 4 µg/L reporting limit during the reporting period.

2.4.3.2.4. Nitrate Concentrations and Distribution

Tpsg-Tps HSU

General trends of nitrate concentrations in the Tpsg-Tps HSU:

- The historical maximum nitrate concentration was 790 mg/L in well W-6CS in 2016.
- Nitrate concentrations decreased to a 2021 maximum of 710 mg/L in the same well in March.

As there are no known nitrate sources associated with Site 300 operations located near this well, it is possible that a sheep ranch that predates Site 300, discovered in a historical photo of the area, may be the source of this localized elevated nitrate. Other wells screened in the Tpsg-Tps HSU had significantly lower nitrate concentrations in 2021, ranging from 130 mg/L in monitor well W-817-2318 to 17 mg/L in monitor well W-823-01, similar to the range observed in 2020.

$Tnbs_2$ HSU

General trends of nitrate concentrations in the $Tnbs_2$ HSU:

- The historical maximum nitrate concentration was 421 mg/L in monitor well W-818-01 in 1994.
- Nitrate concentrations decreased to a current maximum of 120 mg/L in monitor well W-817-2609 in March.

During the reporting period, nitrate was not detected above the reporting limit in 27 routine and duplicate samples collected from off-site water-supply well GALLO1 and was not detected above the 45 mg/L MCL cleanup standard in groundwater from any of the $Tnbs_2$ HSU guard wells. The 2021 nitrate data from $Tnbs_2$ HSU wells continue to support the interpretation that nitrate is being attenuated *in situ* by natural processes, principally reductive denitrification, consistent with MNA. Nitrate concentrations remain below the 45 mg/L MCL cleanup standard in all wells near the southern site boundary where groundwater is present under confined or artesian anoxic conditions, with concentrations ranging from 18 mg/L to under the reporting limit.

$Tnsc_{1b}$ HSU

General trends of nitrate concentrations in the $Tnsc_{1b}$ HSU:

- The historical maximum nitrate concentration was 240 mg/L in extraction well W-829-06 in 2000.

- Nitrate decreased to a current maximum of 74 mg/L in a sample taken from extraction well W-829-06 in October.

Nitrate concentrations for 2021 are similar to those detected in 2020 in extraction well W-829-06. Monitor wells W-829-08 and W-829-1940 were sampled in March and had nitrate concentrations below the reporting limit (0.5 mg/L) and 43 mg/L, respectively.

2.4.3.3. HEPA OU Remediation Optimization Evaluation

Remediation at the HEPA OU is managed by balancing groundwater extraction at the southern Site 300 boundary with upgradient pumping in the source and proximal areas. This strategy is designed to aggressively remediate contaminant source areas, while hydraulically capturing the leading edge of the VOC plume near the Site 300 southern boundary and minimizing the migration of multiple, co-mingled plumes from their respective source areas.

Extraction well W-817-2318 pumps groundwater from the Tpsg-Tps HSU in the area of highest VOC and perchlorate concentrations near Spring 5, downgradient of 817-SRC and adjacent to 817-PRX. Groundwater extraction from the Tpsg-Tps HSU is hampered by the HSU's low permeability, and the dependence of groundwater elevation and spatial distribution on seasonal recharge. In spite of this, TCE concentrations have declined in extraction well W-817-2318 from a historical maximum of 55 µg/L (2007) to a 2021 maximum of 12 µg/L (April).

During 2021, 815-PRX extraction wells W-818-08 and W-818-09 continued to hydraulically capture groundwater with the highest VOC concentrations, and extraction wells W-6ER, W-35C-04, and W-815-2608 continued to capture the leading edge of the VOC plume along the southern Site 300 boundary.

815-SRC extraction wells W-815-02, W-815-04, and W-815-2803, and 817-SRC extraction well W-817-01, continue to extract groundwater from the areas with the highest RDX concentrations. HE compound concentrations have generally exhibited a decreasing trend over the last five years, with some fluctuations in RDX concentrations observed in the vicinity of 815-SRC, likely related to injection of effluent into well W-815-1918 and variations in seasonal recharge.

Perchlorate concentrations in the $Tnbs_2$ HSU during 2021 have declined considerably from concentrations detected in 1998, when monitoring for this COC began. The areas with the highest perchlorate concentrations continue to be located in the vicinity of the 817-SRC and 817-PRX treatment facilities. Perchlorate concentrations in the confined portions of the $Tnbs_2$ HSU near the Site 300 southern boundary continue to be below the reporting limit. Spatial and temporal perchlorate concentration trends suggest perchlorate is being degraded *in situ* by natural processes similar to those confirmed for nitrate natural attenuation (principally bacterially-motivated reduction).

Nitrate concentrations in the confined portions of the $Tnbs_2$ HSU near the Site 300 southern boundary continue to be near or below the reporting limit, demonstrating the continued effectiveness of MNA of nitrate even under pumping conditions.

Throughout the reporting period, pumping from HEPA extraction wells has been effective in capturing COCs and preventing migration of contaminated groundwater any farther toward the Site 300 boundary. During 2021, VOCs were not detected above reporting limits in off-site water-supply well GALLO1, and VOCs in on-site guard wells W-815-2110 and W-815-2111 remained stable at very low concentrations (TCE was detected at concentrations of 1.4 µg/L or below, and *cis*-1,2-DCE was detected at a concentration of 0.52 µg/L in a single routine and duplicate sample

taken from W-815-2111 in December). Upgradient and downgradient pumping will continue to be balanced, so that hydraulic capture at the Site 300 southern boundary is maintained without accelerating migration from upgradient sources. Close monitoring of VOC concentrations in the southern site boundary area will also continue, especially near off-site water-supply well GALLO1.

Recent HE compound detections in monitor well W-818-01 (RDX, 3.2 µg/L in March) and 815-PRX extraction wells W-818-08 and W-818-09 (2.7 µg/L, December, and 1.3 µg/L, October, respectively; both RDX) suggest an expanded influence due to continued pumping of the 815-PRX extraction wells. The spatial extent of these comingled plumes will be closely monitored, and any necessary modifications will be made to extraction wellfield operations to minimize further migration of these plumes toward the Site 300 boundary.

During 2021, the total mass removed from all HEPA treatment facilities included 77 g of VOCs, 36 g of perchlorate, and 85 g of RDX. The volume of treated groundwater decreased by approximately 15% from 2,494,000 gal (2020) to 2,123,500 (2021). Compared to 2020, decreases in VOC (20%), perchlorate (27%), and RDX mass removed (8%) were observed during 2021. These decreases are mostly due to the reduction in operating time experienced by all OU 4 facilities due to ongoing pandemic-related limits on personnel. In 2021, the 815-PRX GWTS, which captures groundwater containing the highest concentrations of VOCs from the $Tnbs_2$ VOC plume, operated for seven months of the year (May-December) extracting groundwater from a single well, W-818-09, due to maintenance at well W-818-08. The 817-PRX GWTS, which extracts groundwater from the highest concentration portion of the $Tnbs_2$ and Tpsg-Tps perchlorate plumes, operated for the majority of the year (nine months) extracting groundwater from W-817-03 only, as well W-817-2803 was secured for maintenance. The 815-SRC GWTS, which extracts groundwater from the highest concentration portion of the $Tnbs_2$ RDX plume, was operational with at least two of the three extraction wells for the entire reporting period and extracted an 18% greater volume of groundwater compared to 2020; the masses of VOCs and RDX removed at this facility remained unchanged from 2020, and the mass of perchlorate removed increased by 75%. Table Summ-1 and Table 2.3 list the mass removed by each individual HEPA treatment facility. Nitrate in the $Tnbs_2$ HSU continues to undergo *in situ* biotransformation to benign nitrogen gas by anaerobic-denitrifying bacteria.

2.4.3.4. HEPA OU Remedy Performance Issues

There were no new issues that affect the performance of the cleanup remedy for the HEPA OU during this reporting period. The remedy continues to be effective and protective of human health and the environment and is making progress toward cleanup.

2.5. Building 850/Pit 7 Complex (OU 5)

Outdoor HE experiments were conducted at the Building 850 Firing Table from the 1950s until 2008. During the time when explosives tests were conducted at Building 850, the firing table was covered with gravel for shock absorption. The firing table was routinely rinsed down with water after each experiment to reduce dust. This practice was discontinued in 2004. Infiltrating direct rainfall, runoff, and rinse water mobilized chemicals from the contaminated gravel to the underlying bedrock and groundwater. Until 1989, gravels from the firing table surface were periodically removed and disposed of in landfills in the northwest part of Site 300, which is now designated as the Pit 7 Complex.

In 2009, a CAMU was constructed adjacent to Building 850 as part of a non-time critical removal action. A total of 27,592 cubic yards of polychlorinated biphenyl- (PCB), dioxin-, and furan-contaminated soil were excavated from the Building 850 Firing Table area, mixed with Portland cement and water, and consolidated and compacted to form the CAMU. Additional information on this removal action is presented in the Building 850 Action Memorandum (Dibley et al., 2008). Design information for the CAMU is presented in the construction subcontractor's 100% design submittal (SCS Engineers, 2009). The inspection and maintenance program for the CAMU is described in Section 3. A map of the Building 850 area within OU 5 showing the locations of Building 850, the CAMU, wells, and other features is presented on Figure 2.5-1.

An *in situ* bioremediation treatability study to irreversibly transform perchlorate in groundwater immediately downgradient of Building 850 to benign end-products commenced in September 2011. Results indicate that the injection of ethyl lactate has resulted in bacterially-motivated reduction of perchlorate and nitrate in the treatment zone to concentrations below reporting limits. A summary of the current status of the treatability study, including rebound monitoring results, is presented in Section 2.5.2.3.

The Pit 7 Complex within OU 5 includes the Pits 3, 4, 5, and 7 Landfills. These landfills were used to dispose of firing table debris and gravel and were constructed by excavating soil and alluvial materials to average depths of 15 to 20 ft (Taffet et al., 1989). The majority of the waste in the pits originated at the firing tables at Buildings 850 and 851. The pit waste included wood, plastic, material, and debris from tent structures, pea gravel, and exploded test assemblies, some of which contained tritium and depleted uranium.

During above-normal rainfall years, the pit waste, vadose zone, and underlying Quaternary alluvium/weathered bedrock (Qal/WBR) HSU were often inundated as residual contamination came into contact with shallow groundwater. Groundwater contaminants include tritium, depleted uranium, perchlorate, nitrate, and VOCs.

In 1992, an engineered cap was constructed over the Pit 7 Landfill (referred to as the Pit 7 Cap) in compliance with Resource Conservation and Recovery Act (RCRA) requirements. The design included interceptor trenches and surface water drainage channels, a top vegetative layer to prevent erosion, a biotic barrier layer to minimize animal burrowing, a clay layer with very low permeability, and a gravel-filled trench on the west side to reduce infiltration of precipitation and shallow subsurface interflow, respectively, that could result in leaching of contaminants. The Pit 7 cap also covers 100% of Pit 4 and approximately 30% of Pit 3. The original compacted native soil cover on most of Pit 3 and all of Pit 5 remains intact.

The Pit 7 DDS, completed in March 2008, was designed to prevent additional releases of COCs from the pits and underlying bedrock to groundwater. There are four components that comprise the DDS:

1. A subsurface drainage network on the western hillslope;
2. Upgraded riprap at the end of the existing north-flowing concrete channel for the Pit 7 Landfill cap;
3. A vegetated surface water diversion swale along the base of the eastern hillslope, along the paved road (Route 4), including several culverts under Route 4 and dirt fire trails; and

4. An upgraded surface water-settling basin at the south end of the existing south-flowing concrete channel for the Pit 7 Landfill cap.

Additional information on the Pit 7 cap and DDS design is presented in the Remedial Design (RD) document for the Pit 7 Complex (Taffet et al., 2008). The detection monitoring, inspection, and maintenance program for the Pit 7 Complex landfills is described in Section 2.5.5.4.

The Pit 7-Source (PIT7-SRC) GWTS began operation in May 2010. During 2021, groundwater was extracted from Qal/WBR HSU wells W-PIT7-2305, W-PIT7-2703, and W-PIT7-2705, and $Tnbs_1/Tnbs_0$ HSU well NC7-64. The current GWTS configuration includes two ion-exchange resin vessels to remove uranium, followed by one ion-exchange resin vessel containing a perchlorate-selective resin, followed by two parallel sets of ion-exchange resin vessels (total of four) containing a nitrate-selective resin, and three aqueous-phase GAC vessels in series to remove VOCs. The treated water, which still contains tritium, is discharged to an infiltration trench.

A map of the Pit 7 Complex area within OU 5 showing the locations of the landfills, DDS, extraction and monitor wells, and the treatment system is presented on Figure 2.5-1. The Building 850 area of OU 5 is discussed in Sections 2.5.1 and 2.5.2. The Pit 7 Complex area of OU 5 is discussed in Sections 2.5.3 through 2.5.5.

2.5.1. Building 850 Area of OU 5 Groundwater Monitoring

The status of 2021 compliance groundwater sampling and analysis at the Building 850 area is presented in Appendix C. Appendix C explains deviations from the sampling plan.

During the second semester of 2021, groundwater monitoring in the Building 850 area was conducted in accordance with the CMP monitoring requirements with the following exceptions: a total of 64 required analyses for 21 wells and one spring were not performed. These analyses were not performed because:

- The wells or spring were dry or there was insufficient water for sample collection,
- There was an issue with sampling equipment, or
- There was limited personnel availability due to the COVID-19 pandemic.

Analytical results and groundwater elevation measurements obtained during 2021 are presented in Attachment 1 and Appendix D, respectively.

Groundwater elevation contour maps for the Qal/WBR and $Tnbs_1/Tnbs_0$ HSUs within the OU are presented on Figures 2.5-2 and 2.5-3, respectively. Groundwater elevations in 2021 in both HSUs are slightly lower than 2020 levels.

2.5.2. Building 850 Area of OU 5 Remediation Progress Analysis

This section is organized into five subsections: contaminant concentrations and distribution, remediation optimization evaluation, enhanced bioremediation treatability study, Building 850 CAMU monitoring, and remedy performance issues.

2.5.2.1. Building 850 Area of OU 5 Contaminant Concentrations and Distribution

In the Building 850 area of OU 5, tritium and perchlorate are the primary COCs detected in groundwater; depleted uranium and nitrate are secondary COCs. These constituents have been identified within the Qal/WBR and $Tnbs_1/Tnbs_0$ HSUs.

Wells W-850-2416 and NC7-69 are located 200 and 500 ft east of the Building 850 Firing Table, respectively. These wells are screened in the deeper $Tnsc_0$ and Tmss HSUs, respectively. They have never contained any COC at concentrations in excess of reporting limits and/or background ranges.

2.5.2.1.1. Tritium Activity Concentrations and Distribution

Tritium activity concentrations in the Building 850 area exceeded the 20,000 pCi/L MCL cleanup standard in one well in 2021. The maximum tritium activity concentrations have decreased from a historical maximum of 566,000 pCi/L (monitor well NC7-28, 1985) to a 2021 maximum of 29,800 pCi/L (December) in new $Tnbs_1/Tnbs_0$ HSU monitor well W-850-3701. Tritium activity concentrations and distribution in groundwater in the Qal/WBR and $Tnbs_1/Tnbs_0$ HSUs in the Building 850 area are discussed below.

Qal/WBR HSU

- Tritium activity concentrations exceeding the 20,000 pCi/L MCL cleanup standard have not been detected in any groundwater samples collected from Qal/WBR HSU monitor wells since 2015.
- The 2021 maximum tritium activity concentration in groundwater collected from the Qal/WBR HSU was 16,600 pCi/L at well W-850-05 (October), located near the eastern edge of the Building 850 Firing Table. The 2021 maximum was a slight increase from the 2020 maximum tritium activity concentration of 16,300 pCi/L in the same well.
- During 2021, tritium activity concentrations in most Qal/WBR HSU monitor wells were similar to 2020 activity concentrations and the extent of groundwater with tritium in excess of background (Figure 2.5-4) was also similar to previous years.

Monitor wells W-PIT2-2301 and W-PIT2-2302, located in Elk Ravine downgradient of the Pit 2 Landfill, are monitored to determine the downgradient extent of tritium in the Qal/WBR HSU in this area. In 2021, neither well had sufficient water to be sampled.

Beginning in 2013, the extent of tritium exceeding the 20,000 pCi/L MCL cleanup standard began to decrease significantly and since the first semester of 2015, tritium activity concentrations throughout the Qal/WBR HSU have remained below the 20,000 pCi/L MCL cleanup standard (Figure 2.5-4). The highest tritium activity concentrations are still detected in wells located immediately downgradient of the Building 850 Firing Table (NC7-70, W-850-2417, W-850-05, NC7-61, and NC7-28) and have generally declined.

$Tnbs_1/Tnbs_0$ HSU

- During 2021, tritium activity concentrations exceeding the 20,000 pCi/L MCL cleanup standard were detected in recently completed monitor well, W-850-3701, which is screened exclusively in the $Tnbs_1/Tnbs_0$ HSU.
- The maximum 2021 tritium activity concentration in the $Tnbs_1/Tnbs_0$ HSU was 29,800 pCi/L (December) in monitor well W-850-3701, located approximately 400 ft downgradient (east) of the Building 850 Firing Table. The 2021 maximum was an increase from the 2020 maximum of 6,070 pCi/L in well W-850-05. This was the first reported tritium activity concentration in excess of the 20,000 pCi/L MCL cleanup standard in the HSU in the Building 850 area since 2014.

- W-850-3701 was drilled and developed in 2021. Samples were collected in October for baseline analytes. Following a result of 25,700 pCi/L (October), confirmatory samples were collected in December yielding an activity concentration of 29,800 pCi/L.
- During 2021, tritium activity concentrations in most $Tnbs_1/Tnbs_0$ HSU monitor wells are similar to 2020 activity concentrations with the exception of W-850-3701. Monitor well W-850-3701 will be sampled for tritium for the next six quarters as part of the standard new well sampling schedule. The extent of groundwater with tritium in excess of background (Figure 2.5-5) was also similar to previous years.

2.5.2.1.2. Uranium Concentrations and Distribution

During 2021, uranium analyses were performed primarily by alpha spectroscopy with selected samples analyzed by Inductively Coupled Plasma-Mass Spectrometry (ICP-MS). High precision uranium isotope data (uranium-235/uranium-238 [$^{235}U/^{238}U$] atom ratio) for determining the presence of depleted uranium are only available by ICP-MS analysis. The presence of depleted uranium is indicated by a $^{235}U/^{238}U$ atom ratio of less than 0.007. Historical uranium isotope data indicate that regions of groundwater containing some added depleted uranium extend downgradient about 1,200 ft within the Qal/WBR HSU and 700 ft within the $Tnbs_1/Tnbs_0$ HSU from the Building 850 Firing Table and have remained relatively stable in extent. Uranium activity concentrations at or above the 20 pCi/L MCL cleanup standard were detected in one well, W-850-2315, in the Building 850 area during 2021. Uranium activity concentrations and distribution in groundwater in the Qal/WBR and $Tnbs_1/Tnbs_0$ HSUs in the Building 850 area are discussed below.

Qal/WBR HSU

- During 2021, total uranium activity concentrations exceeding the 20 pCi/L MCL cleanup standard were not detected in any Qal/WBR HSU wells in the Building 850 area.
- The maximum 2021 total uranium activity concentration was 9.2 pCi/L (May), detected in ethyl lactate injection well W-850-2417, located in the bioremediation treatment zone. The maximum 2021 total uranium activity concentration was slightly higher than the 2020 maximum activity concentration of 7.3 pCi/L detected in well NC7-28, located immediately downgradient of the Building 850 firing table.
- The historical maximum total uranium activity concentration for the Building 850 area is 24 pCi/L (January 2013) in well NC7-28.
- Uranium activity concentrations remained similar to 2020 activity concentrations in all Qal/WBR HSU wells within the Building 850 area (Figure 2.5-6).

$Tnbs_1/Tnbs_0$ HSU

- The maximum 2021 total uranium activity concentration in the $Tnbs_1/Tnbs_0$ HSU was 20.3 pCi/L (May) in monitor well W-850-2315, located approximately 1,400 ft southeast (cross-gradient) of Building 850. Monitor well W-850-2315 was the only $Tnbs_1/Tnbs_0$ HSU well in the Building 850 subarea that yielded a uranium activity concentration in excess of the 20 pCi/L MCL cleanup standard in 2021. The maximum 2021 total uranium activity concentration was a slight decrease from the 2020 maximum of 21 pCi/L from the same well.

- Mass spectrometric data from October 2021 samples from well W-850-2315 continue to indicate a natural $^{235}U/^{238}U$ atom ratio (0.007218).
- W-850-2315 and NC7-29 (19 pCi/L, October) are the only two wells that have ever exceeded the uranium MCL in the $Tnbs_1/Tnbs_0$ HSU in the Building 850 area.
- Uranium activity concentrations remained similar to 2020 activity concentrations in all $Tnbs_1/Tnbs_0$ HSU wells within the Building 850 area (Figure 2.5-7).

2.5.2.1.3. Nitrate Concentrations and Distribution

Nitrate was detected at concentrations at or above the 45 mg/L MCL cleanup standard in 11 wells in the Building 850 area during 2021. Nitrate concentrations and distribution in groundwater in the Qal/WBR and $Tnbs_1/Tnbs_0$ HSUs in the Building 850 area are discussed below. Historical data indicate that groundwater nitrate concentrations in the Qal/WBR and $Tnbs_1/Tnbs_0$ HSUs are limited in extent and relatively stable. Overall, except for the *in situ* bioremediation treatment zone, the distribution, and concentrations of nitrate in groundwater are generally consistent with those observed in previous years.

Qal/WBR HSU

- During 2021, the maximum nitrate concentration measured in a Qal/WBR HSU well was 60 mg/L (May) in monitor well NC7-44, located upgradient of the Building 850 Firing Table. The maximum 2021 nitrate concentration was an increase from the 2020 maximum of 48 mg/L in well W-PIT1-2204 (not sampled during 2021 due to insufficient water).
- In 2021, four wells in the Qal/WBR HSU in the Building 850 area that were sampled for nitrate exceeded the 45 mg/L MCL cleanup standard. Of these wells, three are located within 700 ft downgradient of the Building 850 Firing Table: NC7-11 (54 mg/L, April), NC7-61 (53 mg/L, May), and W-850-2417 (48 mg/L, May). Well NC7-44 (60 mg/L, May) is located approximately 300 ft upgradient.
- The maximum historical nitrate concentration in the Qal/WBR HSU in the Building 850 area was 186 mg/L in well K2-04S (1993), located approximately 1,500 ft east of the Building 850 Firing Table along Doall Ravine.
- During 2021, the spatial extent of groundwater in the Qal/WBR HSU containing nitrate concentrations in excess of the 45 mg/L MCL cleanup standard remained similar to 2020 in the Building 850 area (Figure 2.5-8)

$Tnbs_1/Tnbs_0$ HSU

- The 2021 maximum nitrate concentration in the $Tnbs_1/Tnbs_0$ HSU in the Building 850 area was 180 mg/L (April) in monitor well NC7-29, located southeast and cross-gradient of Building 850 near HE storage Magazine M-80. This is an increase from the 2020 maximum of 64 mg/L in W-PIT1-2209, located 1,400 ft east of the Pit 1 Landfill near Building 804.
- During 2021, samples from seven of the wells in the $Tnbs_1/Tnbs_0$ HSU in the Building 850 area sampled for nitrate exceeded the 45 mg/L MCL cleanup standard. These wells, located southeast of the Pit 2 Landfill, along the west branch of the Elk Ravine Fault, near Building 801 and the Pit 8 Landfill, or south of the northern boundary of Site 300 and corresponding nitrate concentrations are K8-01 (47 mg/L, May), NC2-12S (97 mg/L, May), NC2-19 (55 mg/L, May), NC2-21 (46 mg/L, May), NC7-29 (180 mg/L, April), W-PIT1-2209 (68 mg/L, October), and W-PIT2-1934 (49 mg/L, May).

- The 2021 maximum nitrate concentration of 180 mg/L in well NC7-29 is an increase from the 2020 maximum of 64 mg/L in well W-PIT1-2209; however, well NC7-29 was not sampled in 2020 due to pandemic-related limits on personnel availability.
- During 2021, the extent of groundwater in the $Tnbs_1/Tnbs_0$ HSU containing nitrate concentrations in excess of the 45 mg/L MCL cleanup standard remained similar to 2020 in the Building 850 area (Figure 2.5-9).

2.5.2.1.4. Perchlorate Concentrations and Distribution

During 2021, perchlorate concentrations exceeded the 6 µg/L MCL cleanup standard in 13 wells located east and south (downgradient) of Building 850, and east (downgradient) of Pit 1. Enhanced *in situ* bioremediation treatability testing that was conducted on October 12, October 25, and November 16 in the Building 850 source area has significantly reduced perchlorate concentrations within the treatment zone immediately downgradient of the firing table. Perchlorate concentrations and distribution in groundwater in the Qal/WBR and $Tnbs_1/Tnbs_0$ HSUs in the Building 850 area are discussed below.

Qal/WBR HSU

- During 2021, the maximum perchlorate concentration in Qal/WBR HSU groundwater in the Building 850 area was 39 µg/L (May) in ethyl lactate injection well W-850-2417, a minor decrease from the 2020 maximum of 42 µg/L in the same well.
- The historical maximum perchlorate concentration in Qal/WBR HSU groundwater in the Building 850 area is 92 µg/L (October 2008) in monitor well NC7-28.
- During 2021, samples from ten of the wells screened in the Qal/WBR HSU in the Building 850 area sampled for perchlorate exceeded the 6 ug/L MCL cleanup standard. These wells are located immediately downgradient of Building 850 and along Doall Ravine (with corresponding perchlorate concentrations): NC7-10 (18 µg/L, March), NC7-11 (18 µg/L, April), NC7-28 (19 µg/L, April), NC7-56 (6.4 µg/L, November), NC7-61 (33 µg/L, May), NC7-62 (6.2 µg/L, May), NC7-72 (6.3 µg/L, May), NC7-73 (6.5 µg/L, May), W-850-2313 (11 µg/L, April), and W-850-2417 (39 µg/L, May).
- During 2021, groundwater in the Qal/WBR HSU containing perchlorate concentrations in excess of the 6 µg/L MCL cleanup standard remained similar to 2020 concentrations and extends approximately 1,500 ft downgradient of the Building 850 Firing Table (Figure 2.5-10).

$Tnbs_1/Tnbs_0$ HSU

- During 2021, the maximum perchlorate concentration detected in a well screened exclusively in the $Tnbs_1/Tnbs_0$ HSU in the Building 850 area was 7.4 µg/L (May) at well NC2-17, located southeast of the Pit 2 Landfill. This is a slight decrease from the 2020 maximum of 7.7 µg/L in the same well.
- Samples from three of the wells in the $Tnbs_1/Tnbs_0$ HSU in the Building 850 area that were sampled for perchlorate exceeded the 6 µg/L MCL cleanup standard. These wells are located 1,700 ft southeast (downgradient) of Pit 2, 3,300 ft east (downgradient) of Building 850, and 3,000 ft east (downgradient) of Building 850: NC2-12I (6.8 µg/L, May), NC2-17 (7.4 µg/L, May), and W-850-2145 (6.1 µg/L, October).

- During 2021, the extent of groundwater in the $Tnbs_1/Tnbs_0$ HSU containing perchlorate concentrations in excess of the 6 µg/L MCL cleanup standard remained similar to 2020 for Building 850 area wells (Figure 2.5-11).

The current extent of perchlorate exceeding the 6 µg/L MCL cleanup standard is shown on Figure 2.5-11 and is similar to what was observed in 2020, in relation to wells that are located beyond the Building 850 area, with one exception. As previously reported in the 2020 Annual CMR (Buscheck et al., 2021a), monitor wells W-865-3505 and W-865-3607 exhibited perchlorate concentrations of 5.4 and 32 µg/L (below and in excess of the 6 µg/L MCL cleanup standard), respectively, in 2020. In 2021, well W-865-3505 yielded maximum perchlorate concentrations of 4.9 µg/L in March and May quarterly samples. In 2021, perchlorate was not detected above the reporting limit in quarterly samples from well W-865-3607. The decline in a perchlorate concentration from 32 µg/L to four consecutive quarters of non-detects in W-865-3607 suggests that the 2020 results for this well may be spurious. LLNL will continue to closely monitor perchlorate concentrations in these wells.

2.5.2.1.5. HE Compound Concentrations and Distribution

During 2021, groundwater samples from 45 wells located in and around the Building 850 area were analyzed for HE compounds at typical reporting limits of 1 or 2 µg/L. HMX, RDX and 3-nitrotoluene were detected at concentrations exceeding these reporting limits. The source of HMX, RDX and 3-nitrotoluene is the Building 850 Firing Table. HE compound concentrations and distribution in groundwater in the Qal/WBR and $Tnbs_1/Tnbs_0$ HSUs in the Building 850 area are discussed below.

Qal/WBR HSU

- During 2021, the maximum HMX concentration in the Qal/WBR HSU in the Building 850 area was 11 µg/L (May) in ethyl lactate injection well W-850-2417, an increase from the 2020 maximum of 7 µg/L in well NC7-61.
- During 2021, five wells in the Qal/WBR HSU in the Building 850 area that were sampled for HE yielded HMX concentrations above reporting limits. These wells are located immediately downgradient of Building 850 and along Doall Ravine (with corresponding maximum 2021 HMX concentrations): NC7-10 (2.6 µg/L, April), NC7-11 (1.9 µg/L, April), NC7-28 (7.9 µg/L, October), NC7-61 (7.0 µg/L, October), and W-850-2417 (11 µg/L, May). These concentrations are significantly below the HMX regional tapwater screening level of 1,000 µg/L (U.S. EPA, 2016).
- During 2021, the maximum RDX concentration in the Qal/WBR HSU in the Building 850 area was 5.9 µg/L (May) in ethyl lactate injection well W-850-2417, a minor decrease from the 2020 maximum of 6.1 µg/L in NC7-61.
- During 2021, four wells in the Qal/WBR HSU in the Building 850 that were sampled for HE yielded RDX concentrations above reporting limits. These wells are located immediately downgradient of Building 850 and along Doall Ravine (with corresponding maximum 2021 RDX concentrations): NC7-10 (1.9 µg/L, April), NC7-28 (2.1 µg/L, October), NC7-61 (4 µg/L, May and October), and W-850-2417 (5.9 µg/L, May).
- HE concentrations remained similar to 2020 concentrations in all Qal/WBR HSU Building 850 area wells that were sampled during 2021.

$Tnbs_1/Tnbs_0$ HSU

- During 2021, 3-nitrotoluene was detected above the 2 µg/L reporting limit in $Tnbs_1/Tnbs_0$ HSU well NC7-43 (4 µg/L, October). This is the first detection of 3-nitrotoluene in a well screened exclusively in the $Tnbs_1/Tnbs_0$ HSU downgradient of Building 850.
- In 2017, well NC7-43 yielded 1.1 µg/L of HMX, slightly above the 1 µg/L reporting limit. Although well NC7-43 has not yielded a detection of HMX since 2017, the current reported detection of 3-nitrotoluene in the well suggests that HE compounds are present in the $Tnbs_1/Tnbs_0$ HSU, albeit at very low concentrations. Future monitoring data will clarify the nature of HE compounds in the HSU.
- HE compound concentrations remained similar to 2020 concentrations in all $Tnbs_1/Tnbs_0$ HSU Building 850 area wells that were sampled during 2021.

2.5.2.2. Building 850 Area of OU 5 Remediation Optimization Evaluation

With the exception of the recent data from new well W-850-3701, recent analytical data indicate that natural attenuation (i.e., dispersion, radioactive decay, and a decreasing source term) continues to be effective in maintaining all tritium activity concentrations in groundwater below the 20,000 pCi/L MCL cleanup standard. The highest tritium activity concentrations in groundwater continue to be located directly downgradient of the tritium sources at the Building 850 Firing Table and continue to decline. In general, activity concentrations continue to decline and are significantly below historical highs throughout. The leading edge of the tritium plume is stable within the Site 300 interior and is expected to completely attenuate within the boundaries of Site 300.

The monitoring-only strategy for uranium at Building 850 continues to be protective given that total uranium activity concentrations in groundwater at and downgradient of Building 850 are below the 20 pCi/L MCL cleanup standard and/or are natural, and the areal extent of depleted uranium has not changed during the monitoring period. Temporal trends in $^{235}U/^{238}U$ atom ratios have remained relatively stable.

During 2021, the overall extent and maximum concentrations of nitrate and perchlorate in groundwater are similar to those observed in 2020.

Concentrations of RDX, HMX, and 3-nitrotoluene are low and are confined to the area immediately downgradient of Building 850 and do not exceed any drinking water standards.

2.5.2.3. Building 850 Area of OU 5 Enhanced Bioremediation Treatability Study

The *in situ* perchlorate bioremediation treatability study commenced at Building 850 during the second semester of 2011. The objective of this study is to evaluate the efficacy of *in situ* enhanced bioremediation methods in reducing perchlorate concentrations in the presence of elevated nitrate in Building 850 groundwater. To date, the test has consisted of extracting contaminated groundwater from wells W-850-2417 or NC7-70, mixing this groundwater with dilute ethyl lactate, and injecting this mixture into wells W-850-2417 (2011 and 2012) or NC7-70 (2013 and 2015) to facilitate the *in situ* bioremediation of perchlorate by indigenous bacteria. While awaiting rebound in perchlorate concentrations, the ethyl lactate mixture was not injected into groundwater during 2016-2021. Bioremediation performance is being evaluated primarily at downgradient performance monitor wells NC7-28 and NC7-61.

Perchlorate concentrations in wells NC7-70, W-850-2417, NC7-28, and NC7-61 have decreased from pre-test 2011 concentrations of 45.6, 74, 61.2, and 45 µg/L, respectively, to 2021 concentrations of below the 2 µg/L reporting limit (October), 32 µg/L (October), 24 µg/L (October), and 39 µg/L (October), respectively. The recent data reflect rebound of perchlorate concentrations toward pre-injection levels after over five years since the last injection of ethyl lactate. The persistence of perchlorate concentrations below the 2 µg/L reporting limit in injection well NC7-70 is indicative of a diminished upgradient perchlorate source and the longevity of electron donor ethyl lactate in sustaining perchlorate reduction in the presence of multiple electron acceptors, including DO, nitrate, sulfate, and hydrous ferrous oxide reactive mineral surfaces on the solid matrix within the treatment zone.

Although not specifically targeted for bioremediation, nitrate and uranium are also monitored in injection wells W-850-2417 and NC7-70, and performance monitor well NC7-28. Nitrate concentrations in wells W-850-2417 and NC7-70 have decreased from pre-injection maxima of 52 mg/L, and 57 mg/L, respectively, to 48 mg/L (May) and less than 0.5 mg/L (April), respectively, during 2021. Nitrate concentrations in performance monitor well NC7-28 have decreased from a pre-injection maximum of 88 mg/L to 21 mg/L (October). Although nitrate concentrations remained low in wells NC7-70 and NC7-28, concentrations in well W-850-2417 are back to pre-injection levels.

Uranium activity concentrations in wells W-850-2417, NC7-28, and NC7-70 initially decreased following ethyl lactate injection but fluctuated with some uranium activity concentrations exceeding pre-injection values. Following ethyl lactate injection, decreasing uranium trends appear to result from concurrent reduction of U(VI) species (U^{+6} oxidation state) in groundwater to U(IV) (U^{+4} oxidation state) species, precipitating low solubility mineral solids. Groundwater uranium activity concentration increases observed later likely arose from a combination of dissolution of natural uranium from the rock matrix under low pH conditions and oxidation of reduced uranium minerals and desorption from mineral surfaces, coupled with arrival of pre-existing dissolved uranium from upgradient of the treatment area. As rebound monitoring has continued, current uranium activity concentrations in the Building 850 treatability test wells are generally similar to or lower than those measured before lactate injection began in 2011. Wells NC7-70, W-850-2417, NC7-28, and NC7-61 exhibited total uranium activity concentrations of 0.56 pCi/L (April and October), 9.2 pCi/L (May), 8.7 pCi/L (April), and 3.9 pCi/L (May), respectively, during 2021.

2.5.2.4. Building 850 Corrective Action Management Unit

A CAMU was constructed in the Building 850 area in 2009 as part of the Building 850 Removal Action (Section 2.5). The Building 850 CAMU is inspected and maintained per the requirements of the inspection and maintenance plan (SCS Engineers, 2010).

Improvements to reduce erosion of the CAMU access road took place during the second semester 2021 as part of the road construction along Route 4. Route 4 is immediately east of Building 850 and the Pit 7 Complex landfills. Road base, asphalt, and a short berm were constructed on the lower portion of the CAMU access road. During this construction, the lower portion of the access road was inadvertently excavated 12 to 16 inches into the solidified clean fill in the base of the CAMU. For repairs, the excavated solidified soil was replaced on the lower portion of the access road and was hydrated, re-mixed, and recompacted to the original CAMU specifications before being overlain with road base and asphalt.

Building 850 CAMU Inspection Results

The pre-rainfall season inspection of the CAMU was conducted on December 7, 2021. Some erosion (rilling), grassy vegetation, and animal burrows were observed on the slopes of the CAMU. Proposed corrective actions and repairs to protect the long-term integrity of the CAMU include:

1) Consult with the wildlife biologist and relevant LLNL departments to develop and implement a maintenance plan.
2) Post warning signs to prohibit vehicle traffic on the CAMU.

Building 850 CAMU Maintenance

Maintenance on the Building 850 CAMU during the first semester of 2021 consisted of spraying pre-emergent herbicide on the CAMU to control vegetation. Pre-emergent herbicide will again be applied to the CAMU in early 2022.

2.5.2.5. Building 850 Area of OU 5 Remedy Performance Issues

During this reporting period, there were no new issues that affect the performance of the MNA cleanup remedy for tritium in the Building 850 area. The remedy for tritium continues to be effective and protective of human health and the environment. During 2021, maximum tritium activity concentrations exceeded the 20,000 pCi/L MCL cleanup standard in a single well located 400 ft downgradient of the Building 850 Firing Table. This well will be closely monitored to determine if the elevated tritium activity concentrations persist. Perchlorate, nitrate, uranium, and HE compound concentrations and extent in groundwater downgradient of the Building 850 Firing Table were consistent with those from previous semesters. Groundwater contaminants at the Building 850 area will continue to be closely monitored and reported.

The overall Building 850 area remedy continues to make progress toward cleanup, and to be protective of human health and the environment.

2.5.3. Pit 7 Complex Area of OU 5 Groundwater Treatment System Operations and Monitoring

This section is organized into five subsections: facility performance assessment, operations and maintenance issues, compliance summary, facility sampling plan evaluation and modifications, and treatment facility and extraction wellfield modifications.

2.5.3.1. Pit 7 Complex Area of OU 5 Facility Performance Assessment

The PIT7-Source (SRC) GWTS performed as designed during this reporting period. Its impact on groundwater cleanup is discussed below in Section 2.5.5. The monthly groundwater discharge volumes and rates, and operational hours for the second semester of 2021 are summarized in Table 2.2. The total volume of groundwater extracted and treated, and contaminant masses removed during the reporting period are presented in Table Summ-1. The cumulative volume of groundwater treated and discharged, and masses removed are summarized in Table Summ-2. Analytical results for influent and effluent samples collected during the second semester of 2021 are presented in Table 2.4. The pH measurements are presented in Appendix A.

2.5.3.2. Pit 7 Complex Area of OU 5 Operations and Maintenance Issues

There were no major maintenance issues at the PIT7-SRC GWTS, the Pit 7 Complex landfill covers or cap, or the Pit 7 DDS during 2021. A summary of treatment facility operations is included in Table 2.5. The PIT7-SRC GWTS operated at a reduced capacity during the reporting period until August 5 due to equipment issues. The PIT7-SRC GWTS was secured from August 30 to the end of the reporting period to prevent equipment damage during construction activities on Route 4, the paved road that traverses the east side of the Pit 7 Complex.

DOE/LLNL plans for the PIT7-SRC GWTS to be operating at full capacity early in the first semester of 2022.

The results of inspections of the Pit 7 Complex landfill covers and cap, and related concrete-lined drainage channels are reported in Section 3.6. The results of inspections of the DDS are summarized in Section 2.5.5.4.

2.5.3.3. Pit 7 Complex Area of OU 5 Compliance Summary

The PIT7-SRC GWTS operated in compliance with the RWQCB substantive requirements for wastewater discharge throughout this reporting period.

2.5.3.4. Pit 7 Complex Area of OU 5 Facility Sampling Plan Evaluation and Modifications

The PIT7-SRC treatment facility sampling and analysis plan complies with the monitoring requirements in the CMP/CP. The treatment facility sampling and analysis plan for the first semester of 2022 is presented in Appendix B. No modifications to the plan were made during this reporting period.

2.5.3.5. Pit 7 Complex Area of OU 5 Treatment Facility and Extraction Wellfield Modifications

The wellfield configuration for the PIT7-SRC GWTS has changed several times over the last few years. During 2021, the GWTS received influent from five extraction wells, NC7-64, W-PIT7-2307, W-PIT7-2305, W-PIT7-2703, and W-PIT7-2705. Extraction well NC7-25 was kept off-line, as its operation could result in tritium activity concentrations in effluent exceeding those in the Qal/WBR HSU immediately downgradient of the injection trench. Well NC7-25 was also kept off-line to reduce the potential for depleted uranium to be drawn into the $Tnbs_1/Tnbs_0$ HSU during prolonged pumping of the well. Wells W-PIT7-2704 and W-PIT7-2306 were kept off-line due to insufficient water to operate the wells. Submersible pump replacements for extraction wells W-PIT7-2307, W-PIT7-2704, and W-PIT7-2306 were completed in July 2021.

2.5.4. Pit 7 Complex Area of OU 5 Groundwater Monitoring

The status of the 2021 groundwater compliance sampling and analysis conducted at the Pit 7 Complex area is presented in Appendix C. Appendix C also documents deviations from the sampling plan.

During the second semester of 2021, groundwater monitoring was conducted in accordance with the CMP monitoring requirements with the following exceptions: a total of 33 required analyses for 26 wells and one spring were not performed. These analyses were not performed because:

- The wells or spring were dry or there was insufficient water for sample collection,
- There was an issue with sampling equipment,
- There was an issue with accessibility, or
- There was limited personnel availability due to the COVID-19 pandemic.

Groundwater elevation contour maps for the Qal/WBR and $Tnbs_1/Tnbs_0$ HSUs within the OU are presented on Figures 2.5-2 and 2.5-3, respectively. Groundwater elevations in 2021 in both HSUs are slightly lower than 2020 levels.

2.5.5. Pit 7 Complex Area of OU 5 Remediation Progress Analysis

This section is organized into five subsections: mass removal, analysis of contaminant distribution and concentration trends, remediation optimization and performance evaluation, Pit 7 Complex DDS, and remedy performance issues.

2.5.5.1. Pit 7 Complex Area of OU 5 Mass Removal

The monthly groundwater mass removal estimates for the second semester of 2021 are summarized in Table 2.3. The total mass removed during the reporting period and cumulative mass estimates are summarized in Table Summ-1 and Table Summ-2, respectively.

2.5.5.2. Pit 7 Complex Area of OU 5 Contaminant Concentrations and Distribution

In the Pit 7 Complex area of OU 5, tritium is the primary COC in groundwater, and uranium, perchlorate, nitrate, and VOCs are secondary COCs. These constituents have been identified within the Qal/WBR and $Tnbs_1/Tnbs_0$ HSUs. The locations of the wells discussed in the following text appear on the Building 850 and Pit 7 Complex area site map (Figure 2.5-1).

2.5.5.2.1. Tritium Activity Concentrations and Distribution

Commingled plumes of tritium in groundwater extend from Pit 3 and Pit 5 Landfill sources. The Pit 7 Landfill is not an apparent source of tritium to groundwater, as most of the tritium-bearing experiments at Site 300 were conducted prior to its opening in 1979 (Taffet et al., 2008). Monitor well NC7-48, located directly downgradient of Pit 7 and upgradient of Pit 3, has generally yielded groundwater samples that contain tritium activity concentrations within background ranges (i.e., below the 100 pCi/L reporting limit). The tritium activity concentration in the groundwater sample collected from well NC7-48 during the second semester of 2021 (December) was also below 100 pCi/L. Tritium activity concentrations and distribution in groundwater in the Qal/WBR and $Tnbs_1/Tnbs_0$ HSUs in the Pit 7 Complex area are discussed below. In general, tritium activity concentrations continue to slowly decrease and the extents in excess of background activity concentrations in both HSUs remain constant to decreasing.

Qal/WBR HSU

- Tritium activity concentrations in Qal/WBR HSU groundwater in the Pit 7 Complex area have decreased from a historical maximum of 2,660,000 pCi/L (well NC7-63, 1998) to a 2021 maximum of 78,900 pCi/L (March) in well NC7-51, located approximately 100 ft downgradient (east) of Pit 3 and Pit 5.

- The 2021 maximum tritium activity concentration in Qal/WBR HSU groundwater is a decrease from the 2020 maximum tritium activity concentration of 92,800 pCi/L in well NC7-51.
- Ten of the wells in the Qal/WBR HSU that were sampled for tritium during 2021 contained tritium equal to or in excess of the 20,000 pCi/L tritium MCL cleanup standard. These wells (and corresponding tritium activity concentrations) were K7-01 (20,000 pCi/L, May), NC7-21 (24,200 pCi/L, November), NC7-40 (45,900 pCi/L, March), NC7-51 (78,900 pCi/L, March), NC7-64 (72,800 pCi/L, December), W-PIT7-03 (58,500 pCi/L, March), W-PIT7-1918 (34,200 pCi/L, December), W-PIT7-2305 (30,300 pCi/L, December), W-PIT7-2703 (64,200 pCi/L, January), and W-PIT7-2705 (25,400 pCi/L, January).
- Tritium activity concentrations remained similar to 2020 activity concentrations or decreased in all Qal/WBR HSU Pit 7 Complex wells that were sampled during 2021 (Figure 2.5-4) compared to 2020 data.

$Tnbs_1/Tnbs_0$ HSU

- In the Pit 7 Complex area, tritium activity concentrations in $Tnbs_1/Tnbs_0$ HSU groundwater have decreased from a historical maximum of 770,000 pCi/L (1999) to a 2021 maximum of 171,000 pCi/L (December) in well NC7-25, located about 250 ft downgradient (northeast) of the Pit 3 Landfill.
- The 2021 maximum tritium activity concentration is a slight increase from the 2020 maximum Pit 7 Complex tritium activity concentration in the $Tnbs_1/Tnbs_0$ HSU of 167,000 pCi/L, in the same well, NC7-25.
- Five of the wells in the $Tnbs_1/Tnbs_0$ HSU that were sampled for tritium during 2021 contained tritium in excess of the 20,000 pCi/L MCL cleanup standard. These wells (and corresponding tritium activity concentrations) were K7-03 (36,600 pCi/L, April), NC7-25 (171,000 pCi/L, December), W-PIT7-13 (28,500 pCi/L, December), W-PIT7-2307 (32,100 pCi/L, December), and W-PIT7-3406 (105,000 pCi/L, December).
- Tritium activity concentrations remained similar to 2020 activity concentrations or decreased in all $Tnbs_1/Tnbs_0$ HSU Pit 7 wells that were sampled during 2021 (Figure 2.5-5) compared to 2020 data.

2.5.5.2.2. Uranium Concentrations and Distribution

Uranium activities and distribution in groundwater in the Qal/WBR and $Tnbs_1/Tnbs_0$ HSUs in the Pit 7 Complex area are discussed below. As was the case for the Building 850 area of OU 5, total uranium and individual isotope activity concentrations were obtained by alpha spectroscopy with selected samples analyzed by ICP-MS for defining total uranium activity concentration and isotope atom ratios in samples from monitor wells.

Qal/WBR HSU

- Total uranium activity concentrations in Qal/WBR HSU groundwater in the Pit 7 Complex area have decreased from a historical maximum of 781 pCi/L (monitor well NC7-40, 1998) to a 2021 maximum of 123 pCi/L (December) in well NC7-64 (with a depleted $^{235}U/^{238}U$

atom ratio of 0.006155). Well NC7-64 is located immediately downgradient of Pit 3 (see Figure 2.5-1).

- The 2021 maximum total uranium activity concentration is a minor decrease from the 2020 maximum Pit 7 Complex total uranium activity concentration in the Qal/WBR HSU of 130 pCi/L, also in well NC7-64.
- Eight Qal/WBR HSU wells in the Pit 7 Complex area exhibited total uranium activity concentrations exceeding the 20 pCi/L MCL cleanup standard during 2021. These wells (and corresponding uranium activity concentrations) were NC7-64 (123 pCi/L, December), W-PIT7-03 (33.7 pCi/L, June), W-PIT7-1917 (71 pCi/L, April), W-PIT7-2703 (121.4 pCi/L, December), W-PIT7-2705 (37.8 pCi/L, January), NC7-40 (110 pCi/L, June), NC7-51 (55 pCi/L, June), and W-PIT7-1918 (48 pCi/L, April).
- Uranium activity concentrations remained similar to 2020 activity concentrations in all Qal/WBR HSU Pit 7 wells that were sampled during 2021 (Figure 2.5-6) compared to 2020.

All of the wells where uranium activity concentrations exceeded the 20 pCi/L MCL cleanup standard have historically shown $^{235}U/^{238}U$ atom ratios indicating some depleted uranium in the groundwater. The spatial extent of shallow groundwater impacted by depleted uranium has remained relatively stable for the past two decades. Historically, areas of depleted uranium in groundwater have been bounded by wells that exhibit $^{235}U/^{238}U$ atom ratios indicative of natural uranium. Mass spectrometric analytical data for samples collected to date do not indicate any significant change in the footprint of shallow groundwater (Qal/WBR HSU) impacted by depleted uranium. Sorption and ion-exchange on aquifer mineral surfaces are likely responsible for retarding and attenuating the migration of depleted uranium in groundwater in comparison to conservative contaminants, such as tritium.

$Tnbs_1/Tnbs_0$ HSU

- During 2021, two wells screened in the $Tnbs_1/Tnbs_0$ HSU contained groundwater with total uranium activity concentrations in excess of the 20 pCi/L MCL cleanup standard during 2021. These were extraction (currently monitor) well NC7-25 (40 pCi/L, December) and extraction well W-PIT7-3406 (22 pCi/L, June). Both wells exhibited $^{235}U/^{238}U$ atom ratios indicative of natural uranium (0.0072) in December and June, respectively. Both W-PIT7-3406 and NC7-25 are approximately 200 ft downgradient of Pit 3.
- The 2021 uranium activity concentrations are a decrease from the historical $Tnbs_1/Tnbs_0$ HSU maximum activity concentration of 100 pCi/L (October 2014) detected in well NC7-25 when it was first converted from a monitor well to an extraction well.
- The 2021 maximum total uranium activity concentration is a very slight increase from the 2020 maximum total uranium activity concentration in the $Tnbs_1/Tnbs_0$ HSU of 39 pCi/L in well NC7-25 to a 2021 maximum of 40 pCi/L in the same well.

- Uranium activity concentrations remained similar to 2020 activity concentrations in all $Tnbs_1/Tnbs_0$ HSU wells that were sampled during 2021 (Figure 2.5-7).

2.5.5.2.3. Nitrate Concentrations and Distribution

Nitrate concentrations and distribution in groundwater in the Qal/WBR and $Tnbs_1/Tnbs_0$ HSUs in the Pit 7 Complex area are discussed below.

Qal/WBR HSU

- Nitrate concentrations in Qal/WBR HSU groundwater in the Pit 7 Complex area have decreased from a historical maximum of 140 mg/L (monitor well W-PIT7-2305, 2017) to a 2021 maximum of 55 mg/L (May) in monitor well K7-01, located immediately downgradient of Pit 5.
- The 2021 maximum is a minor increase from the 2020 maximum of 54 mg/L in well W-PIT7-2305, located 20 ft upgradient of K7-01.
- During 2021, four Qal/WBR HSU wells in the Pit 7 Complex area contained nitrate concentrations equal to or above the 45 mg/L MCL cleanup standard. These wells (and corresponding nitrate concentrations) were K7-01 (55 mg/L, May), NC7-64 (50 mg/L, April), W-PIT7-2305 (54 mg/L, December), and W-PIT7-2703 (45 mg/L, January).
- Nitrate concentrations remained similar to 2020 concentrations or decreased in all Qal/WBR HSU Pit 7 Complex area wells that were sampled during 2021 (Figure 2.5-8).

$Tnbs_1/Tnbs_0$ HSU

- Nitrate concentrations in $Tnbs_1/Tnbs_0$ HSU groundwater in the Pit 7 Complex area have decreased from a historical maximum of 77 mg/L in well NC7-25 (2002) to a 2021 maximum of 48 mg/L (April) also in well NC7-25, located approximately 300 ft east (downgradient) of Pit 3.
- During 2021, nitrate was detected above the 45 mg/L MCL cleanup standard in only one $Tnbs_1/Tnbs_0$ HSU well, NC7-25. Nitrate was not detected above the 45 mg/L MCL cleanup standard in any $Tnbs_1/Tnbs_0$ HSU well during 2020; this may be attributed to incomplete sampling resulting from pandemic-related limits on personnel availability.
- Nitrate concentrations remained similar to 2020 concentrations in all $Tnbs_1/Tnbs_0$ HSU Pit 7 wells that were sampled during 2021 (Figure 2.5-9).

2.5.5.2.4. Perchlorate Concentrations and Distribution

Perchlorate concentrations and distribution in groundwater in the Qal/WBR and $Tnbs_1/Tnbs_0$ HSUs in the Pit 7 Complex area are discussed below.

Qal/WBR HSU

- Perchlorate concentrations in Qal/WBR HSU groundwater in the Pit 7 Complex area have exhibited generally stable to decreasing trends from a historical maximum of 40 µg/L in extraction well W-PIT7-2306 (2009) to a 2021 maximum of 12 µg/L (May) in monitor well NC7-34, located between Pits 3 and 5, and 12 µg/L (December) in extraction well W-PIT7-2305, located immediately downgradient of Pit 5.
- The 2021 maximum is a minor increase from the 2020 maximum of 9.1 µg/L in well W-PIT7-1918; this may be attributed to incomplete sampling resulting from pandemic-related limits on personnel availability.

- During 2021, ten wells screened in the Qal/WBR HSU in the Pit 7 Complex exhibited perchlorate concentrations at or above the 6 µg/L MCL cleanup standard. These wells (and corresponding perchlorate concentrations) were K7-01 (8.1 µg/L, May), NC7-34 (12 µg/L, May), NC7-40 (9.5 µg/L, June), NC7-64 (7.5 µg/L, December), W-PIT7-03 (8.8 µg/L, June), W-PIT7-1918 (9.2 µg/L, April and November), W-PIT7-2305 (12 µg/L, December), W-PIT7-2703 (8.2 µg/L, December), W-PIT7-2704 (9.2 µg/L, April), and W-PIT7-2705 (11 µg/L, December).
- Perchlorate concentrations remained similar to 2020 concentrations in all Qal/WBR HSU Pit 7 wells that were sampled during 2021 (Figure 2.5-10).

$Tnbs_1$/$Tnbs_0$ HSU

- Perchlorate concentrations in $Tnbs_1$/$Tnbs_0$ HSU groundwater have decreased from a historical maximum of 29 µg/L in monitor well K7-03 (2005) to a 2021 maximum of 11 µg/L in monitor well W-PIT7-3406 (June and December) and monitor well NC7-68 (June), located immediately downgradient of Pit 5.
- The 2021 maximum perchlorate concentration is a minor increase from the 2020 maximum Pit 7 Complex perchlorate concentration in the $Tnbs_1$/$Tnbs_0$ HSU of 9.2 µg/L in W-PIT7-3406.
- During 2021, four of the wells screened in the $Tnbs_1$/$Tnbs_0$ HSU in the Pit 7 Complex exhibited perchlorate concentrations at or above the 6 µg/L MCL cleanup standard. These wells (and corresponding perchlorate concentrations) were NC7-25 (9 µg/L, December), NC7-68 (11 µg/L, June), W-PIT7-2307 (9.2 µg/L, December), and W-PIT7-3406 (11 µg/L, June and December).
- Perchlorate concentrations remained similar to 2020 concentrations in all $Tnbs_1$/$Tnbs_0$ HSU Pit 7 wells that were sampled during 2021 (Figure 2.5-11).

2.5.5.2.5. VOC Concentrations and Distribution

The VOC COCs in Pit 7 Complex groundwater include TCE and 1,1-DCE. VOC concentrations and distribution in groundwater in the Qal/WBR and $Tnbs_1$/$Tnbs_0$ HSUs in the Pit 7 Complex are discussed below. Because of the limited number of wells in the Pit 7 Complex that yield VOC concentrations in excess of reporting limits and MCL cleanup standards, maps depicting these data are not included in the CMRs.

Qal/WBR HSU

- During 2021, TVOC concentrations exceeding the individual compound 0.5 µg/L reporting limit were detected in one Qal/WBR HSU well, NC7-51, at 0.63 µg/L (all TCE, June). Monitor well NC7-51 is located immediately downgradient of Pit 3.
- TVOC concentrations in Qal/WBR HSU groundwater in the Pit 7 Complex area have decreased from a historical maximum of 21 µg/L in 1995 in monitor well NC7-51, comprised of 15 µg/L of TCE and 6.2 µg/L of 1,1-DCE to the 2021 maximum of 0.63 µg/L in well NC7-51 comprised entirely of TCE (June).
- The 2021 TVOC detections are an increase from the lack of detections of any VOCs in 2020 in any Qal/WBR HSU wells. This may be attributed to incomplete sampling in 2020 resulting from pandemic-related limits on personnel availability.

- VOC concentrations remained similar to 2020 concentrations in all Qal/WBR HSU Pit 7 wells that were sampled during 2021.

$Tnbs_1$/$Tnbs_0$ HSU

- During 2021, TVOC concentrations exceeding the individual compound 0.5 µg/L reporting limit were detected in two Pit 7 Complex area $Tnbs_1$/$Tnbs_0$ HSU wells. Monitor well K7-03 contained 1.1 µg/L of TCE (April) and W-PIT7-2307 contained 4 µg/L of TVOCs (3 µg/L of TCE and 1 µg/L of 1,1-DCE in December); both monitor wells are located immediately downgradient of Pit 5.
- TVOC concentrations in the $Tnbs_1$/$Tnbs_0$ HSU have decreased from the historical maximum of 15.2 µg/L (8.7 µg/L of TCE, 4.5 µg/L of 1,2-DCE, 0.8 µg/L of PCE, and 1.2 µg/L of 1,1,1-TCA) measured in a 1985 groundwater sample collected from well K7-03 to 4 µg/L this semester (December) in W-PIT7-2307.
- The 2021 TVOC detections are an increase from the single detection of TVOCs in Pit 7 Complex area $Tnbs_1$/$Tnbs_0$ HSU wells in 2020 in extraction well W-PIT7-2307 (3.2 µg/L TCE and 1 µg/L 1,1-DCE). This may be attributed to incomplete sampling in 2020 resulting from pandemic-related limits on personnel availability.
- VOC concentrations remained similar to 2020 concentrations in all $Tnbs_1$/$Tnbs_0$ HSU Pit 7 wells that were sampled during 2021.

2.5.5.3. Pit 7 Complex Area of OU 5 Remediation Optimization and Performance Evaluation

The PIT7-SRC GWTS began operation in May 2010. During 2021, groundwater was extracted from Qal/WBR HSU wells NC7-64, W-PIT7-2305, W-PIT7-2703, and W-PIT7-2705. The volume of groundwater extracted and treated at PIT7-SRC during the second semester of 2021 was 6,869 gal. The masses of COCs removed during 2021 are summarized in Table Summ-1. During 2021, 0.11 g of VOCs, 0.55 g of perchlorate, 3.0 kg of nitrate, and 2.6 g of uranium were removed from the extracted groundwater (Table Summ-1).

During 2021, the PIT7-SRC effluent compliance samples did not contain any COCs (e.g., nitrate, perchlorate, uranium, VOCs) in excess of effluent discharge limits.

The total rainfall of 2016-2017 was the highest since the Pit 7 DDS was installed in 2008. The evaluation of the performance of the DDS in response to that rainfall, as discussed in the East/West Firing Areas Five-Year Review (Taffet et al., 2019), indicated that: 1) the DDS did not appear to reduce groundwater elevation response to high rainfall events when compared to response to historical rainfall events, 2) groundwater rose into pit waste and underlying contaminated bedrock, and 3) increasing COC concentration trends were observed for four quarters in key downgradient wells; these factors indicate that the DDS performance criteria were not met. Despite the release of COCs to groundwater in 2017, the extents of COCs in excess of MCL cleanup standards and background concentrations have not expanded and natural attenuation of all COCs continues to occur within less than 1,500 ft of the landfills, as supported by the 2017, 2018, 2019, 2020, and 2021 groundwater monitoring results. Monitoring will continue to provide data to verify whether this natural attenuation, the limited extent of these COCs in excess of MCL cleanup standards and background, and long-term decreasing trends in COC concentrations continue.

The road and drainage were improved during the second semester of 2021 to prevent sediment accumulation on Route 4, which runs immediately east of Pits 3 and 5. Improvements included Route 4 pavement slope upgrades to hasten surface runoff flow into the vegetated swale on the east side of the road and to reduce sediment accumulating on the road during storm events. A new drainage ditch with a permeable bottom was also installed on the west side of Route 4, immediately east of Pits 3 and 5. This work was not conducted as part of the ongoing Pit 7 DDS engineering evaluation, and it is not a new component of the approved CERCLA remedy.

Concentrations of COCs will continue to be closely monitored in downgradient performance monitor wells. Spatial and temporal COC trends in these wells will continue to be used to determine the relative magnitude of any future releases to groundwater and the distribution of localized residual vadose zone COC sources within and beneath the pits.

2.5.5.4. Pit 7 Complex Area Drainage Diversion System

The DDS is inspected and maintained per the requirements of the inspection and maintenance plan (Taffet et al.,2008).

Drainage Diversion System Inspection Results

Monthly rainy season and post-storm inspections were performed routinely during the second semester of 2021. The DDS was inspected on October 12, October 25, November 16, and December 14, 2021. During road construction on Route 4, rocks were temporarily placed in a portion of the vegetated swale immediately east of Route 4. The rocks were removed by the end of the road construction. This minor issue was identified on the October 12, October 25, and November 16 inspection forms. All other DDS components were determined to be satisfactory.

Drainage Diversion System Maintenance

Activities included removing tumbleweeds from the southern settling basin area, the southern rip-rap, several culverts, the vegetated swale, and the northern rip-rap.

2.5.5.5. Pit 7 Complex Area of OU 5 Remedy Performance Issues

Efforts to bring off-line extraction wells back online at the PIT7-SRC GWTS were conducted successfully during the second semester of 2021. The PIT7-SRC GWTS will continue to be operated and maintained to reduce the concentrations of uranium, nitrate, perchlorate, and VOCs in groundwater. While DOE/LLNL continues to evaluate opportunities to optimize the efficiency and effectiveness of the GWTS to improve operations and expedite cleanup, optimization of this facility is limited by the hydraulic characteristics of the HSUs and the availability of groundwater to treat.

The overall Pit 7 Complex remedy continues to make progress toward cleanup, and to be protective of human health and the environment.

2.6. Building 854 (OU 6)

The Building 854 area has been used to test the stability of weapons and weapon components under various environmental conditions, including mechanical and thermal stresses. A map of the Building 854 OU showing the locations of monitor and extraction wells and treatment facilities is presented on Figure 2.6-1.

Two GWTSs are currently operated in the Building 854 OU: 854-SRC and 854-PRX. One GWES is operated in the Building 854 OU: 854-Distal (DIS). One SVTS is also operated as part of the 854-SRC treatment facility.

The 854-SRC GWTS, which began operation in December 1999 to remove VOCs and perchlorate from groundwater, was upgraded in 2016. While operating during 2021, the flow rates for wells W-854-2218 and W-854-02 averaged approximately 4 gpm and 1 gpm, respectively. The system includes a particulate filtration system, two ion-exchange resin columns connected in series for perchlorate removal, and three aqueous-phase GAC vessels connected in series for VOC removal. Nitrate-bearing treated effluent is discharged via a misting tower on to the landscape for uptake and utilization of the nitrate by indigenous grasses.

Soil vapor treatment began at 854-SRC in November 2005. While operating during 2021, soil vapor was extracted from one SVE well, W-854-1834, at an approximate flow rate of 37 scfm. This system consists of a rotary-lobe blower to create a vacuum at the wellhead and a series of pipes leading to three vapor-phase GAC vessels that remove VOCs from extracted soil vapor. Treated vapors are discharged to the atmosphere under a permit issued by the SJVAPCD.

The 854-PRX GWTS began operation in November 2000 to remove VOCs, nitrate, and perchlorate from groundwater. During 2021, groundwater was extracted at a flow rate of approximately 3 gpm from a single extraction well, W-854-03, located southeast of the Building 854 area. The GWTS configuration includes a particulate filtration system, two ion-exchange resin columns connected in series for perchlorate removal, and three aqueous-phase GAC vessels connected in series for VOC removal. Additionally, there is an in-line sensor to monitor real-time nitrate concentrations in extracted groundwater before treatment.

Initially, from July 2006 to July 2019, the 854-DIS GWES operated as a GWTS, removing VOCs and perchlorate from groundwater. It was configured with two ion-exchange resin columns connected in series for perchlorate treatment, followed by three aqueous-phase GAC vessels connected in series for VOC removal prior to discharge to an infiltration trench. As proposed by DOE/LLNL and agreed upon by the regulatory agencies at the June 14, 2018, RPM meeting, because of the low volumes of water treated at this location, the GWTS was converted to a GWES, similar to the Building 817-SRC and 829-SRC systems. All treatment media and components were subsequently removed from the system and a collection tank was added. These engineering modifications and upgrades were completed in July 2019. Groundwater is extracted from well W-854-2139, which operates cyclically. When operating during 2021, the flow rate was less than 20 gal per month due to pump control system issues. The GWES consists of the single well and a collection tank. Extracted water is regularly transferred to the 854-SRC GWTS (or other approved treatment system when needed) for treatment. Because of the control system issues, the 854-DIS GWES was secured on June 24 pending engineering modifications to repair the control system.

2.6.1. Building 854 OU Groundwater Treatment System Operations and Monitoring

2.6.1.1. Building 854 OU Compliance Summary

During 2021, the 854-SRC and 854-PRX treatment facilities operated in compliance with the RWQCB substantive requirements for wastewater discharge; and the 854-SRC SVTS operated in compliance with the SJVAPCD permit.

2.6.1.2. Building 854 OU Operations and Maintenance Issues

Information concerning 854-SRC, 854-PRX, and 854-DIS facility operations and maintenance during 2021 is presented in Table 2.5.

2.6.1.3. Building 854 OU Facility Performance Assessment

The monthly groundwater discharge volumes and operational hours for the second semester of 2021 are summarized in Table 2.2. The total volume of groundwater treated, and masses removed during the reporting period are presented in Table Summ-1. The cumulative volume of groundwater treated and discharged, and the masses removed are summarized in Table Summ-2. Analytical results for influent and effluent samples collected during the second semester of 2021 are presented in Table 2.4. The pH measurements are presented in Appendix A.

2.6.1.4. Building 854 OU Treatment Facility and Extraction Wellfield Modifications

During 2021, no treatment facility or extraction wellfield modifications were performed on the 854-SRC or 854-PRX facilities. The 854-DIS GWES was secured on June 24 to accommodate engineering modifications to address equipment issues, specifically the controls system, while at the same time adding remote data collection. The work began during the second semester of 2021.

2.6.2. Building 854 OU Groundwater and Surface Water Monitoring

The status of the annual groundwater and surface water sampling and analysis that has been conducted at the Building 854 area during 2021 is presented in Appendix C. This table explains any deviations from the sampling plan.

During the reporting period, 235 analyses from 39 wells or springs were required per CMP monitoring requirements. Monitoring was conducted in accordance with the CMP monitoring requirements, with the exception that 24 required analyses from eight different wells or springs were not performed, because the wells or springs were dry or contained insufficient water to collect the samples.

2.6.3. Building 854 OU Remediation Progress Analysis

This section is organized into four subsections: mass removal, analysis of contaminant distribution and concentration trends, remediation optimization evaluation, and remedy performance issues.

2.6.3.1. Building 854 OU Mass Removal

The monthly groundwater and soil vapor mass removal estimates for the second semester of 2021 are summarized in Table 2.3. The total mass removed during the reporting period and cumulative mass estimates are summarized in Table Summ-1 and Table Summ-2, respectively.

2.6.3.2. Building 854 OU Contaminant Concentrations and Distribution

At the Building 854 OU, TCE and perchlorate are the primary COCs detected in groundwater; nitrate is a secondary COC. These COCs have been detected primarily in the $Tnbs_1/Tnsc_0$ HSU. The locations of the wells discussed in the following text are shown on the Building 854 OU site map (Figure 2.6-1).

A groundwater potentiometric surface map for the $Tnbs_1/Tnsc_0$ HSU from the second semester of 2021 is provided in Figure 2.6-2. A TVOC isoconcentration contour map and individual VOC concentrations for the $Tnbs_1/Tnsc_0$ HSU is shown on Figure 2.6-3. A perchlorate isoconcentration

contour map for the $Tnbs_1/Tnsc_0$ HSU is presented on Figure 2.6-4. A map showing nitrate concentrations for the $Tnbs_1/Tnsc_0$ HSU is shown on Figure 2.6-5. Groundwater elevations measured during 2021 are posted for the $Qls/Tnbs_1$ HSU on Figure 2.6-6.

2.6.3.2.1. VOC Concentrations and Distribution

$Qls/Tnbs_1$ HSU

General trends in VOC concentrations in groundwater in the $Qls/Tnbs_1$ HSU:

- Well W-854-10 was the only $Qls/Tnbs_1$ location where VOCs are present above reporting limits.
- The historical maximum TVOC concentration is 60 µg/L (November 2015) in well W-854-10.
- TVOC concentrations increased during 2021 from 10 µg/L (April) to 44 µg/L (entirely TCE) in well W-854-10 (November).
- During 2021, TCE was the only VOC detected in wells screened in the $Qls/Tnbs_1$ HSU in the Building 854 OU.
- VOC concentration trends remained stable during 2021. The spatial distribution of TVOC concentrations above the 0.5 µg/L reporting limit remains very similar to the 2020 distribution.

During 2021, VOCs were only detected above reporting limits in one $Qls/Tnbs_1$ HSU well, W-854-10. TVOC concentrations in groundwater in this well have been variable since 2006, ranging from the historical maximum of 60 µg/L (2015) to a first semester 2021 maximum of 10 µg/L (April), and rising again in the second semester of 2021 to 44 µg/L (November). This variability is concurrent with a general decline in water levels due to drought conditions. During 2021, groundwater levels at well W-854-10 dropped approximately two ft, approximately equal to the previous lowest water levels in 2015, when VOC concentrations were also at the highest (60 µg/L). It is possible that residual VOCs in the vadose zone are released to groundwater when water levels briefly rise during the wet season (even in relatively dry years more representative of drought conditions). During years with higher water levels, VOCs released to groundwater may have been diluted more as a result of the thicker saturated zone, resulting in lower concentrations in the past. This scenario may explain the current sporadic higher concentrations amid the lower water levels.

$Tnbs_1/Tnsc_0$ HSU Groundwater

General trends of VOC concentrations in groundwater in the $Tnbs_1/Tnsc_0$ HSU:

- The historical maximum TVOC concentration is 2,900 µg/L in extraction well W-854-02 (May 1997).
- TCE concentrations decreased to a current maximum of 64 µg/L (entirely TCE) in well W-854-02 (July).
- The VOC *cis*-1,2 DCE was only detected in two wells, with a current maximum of 15 µg/L in well W-854-17; no other VOCs were detected in Building 854 area wells during 2021.
- The 2021 spatial distribution of TVOC concentrations above the 0.5 µg/L reporting limit remained very similar to the 2020 distribution.

VOC concentrations in groundwater remained stable in the 854-SRC area during 2021, with no apparent increasing or decreasing trends. During 2021, only one well in the 854-SRC area contained VOCs other than TCE: W-854-17. Monitor well W-854-17 contained 15 µg/L of *cis*-1,2 DCE (April), above its 6 µg/L MCL cleanup standard. The overall extent of VOCs in excess of the 0.5 µg/L reporting limit has remained relatively stable since remediation began. However, the extent of the northern VOC plume with concentrations greater than 50 µg/L has decreased and is currently limited to the immediate vicinity of the Building 854-SRC area. TVOC concentrations in $Tnbs_1/Tnsc_0$ HSU groundwater have declined from a historical pre-remediation maximum of 2,900 µg/L (extraction well W-854-02, 1997) to a 2021 maximum concentration of 64 µg/L in the same well (July). TVOC concentrations in the other wells sampled during 2021 were similar to those in 2020

At the 854-PRX area, groundwater TVOC (all TCE) concentrations steadily decreased from 19 µg/L (April 2013) to 3.5 µg/L (October 2019) in extraction well W-854-03 as a consequence of extraction and treatment. During 2020, when the well did not pump a significant volume of groundwater, TCE concentrations slightly rebounded to 11 µg/L (August). During 2021, with continuous operation of this extraction well, concentrations in the four quarterly samples steadily decreased from 11 µg/L (January) to 3 µg/L (October). TCE concentrations at nearby monitor well W-854-3405 have ranged from 3.6 µg/L (November 2018) to 5.9 µg/L (April 2021). This well did not exhibit the recent rebounds observed in well W-854-03; however, having been installed in 2018, the analytical history of this monitor well is relatively short, and it will continue to be monitored closely.

Immediately downgradient of the 854-PRX GWTS, VOC concentrations in monitor well W-854-1823 and other nearby wells remained below their respective reporting limits during the reporting period.

The high-concentration portion of the southern VOC plume is located in the vicinity of Well 13, a former water-supply well adjacent to the 854-DIS GWES. The southern plume extends south from this area toward Spring 10 and Spring 11. TCE has been sporadically detected since 1982 at Spring 10 at concentrations of up to 32 µg/L (2000) and at Spring 11 at concentrations of up to 2.6 µg/L (2015). Spring 10 has been dry since 2011 and Spring 11 has been dry since 2018. In the 854-DIS area, VOC concentrations remained stable during the reporting period. The extent of the southern VOC plume with concentrations greater than 10 µg/L has decreased since remediation began. Concentrations generally continue to exhibit a decreasing trend, except for well W-854-07; TCE concentrations in this well ranged from 18 µg/L to 58 µg/L from 1998 to 2016. TCE concentrations had increased at monitor well W-854-07 from the 2016 maximum of 6.5 µg/L (November) to the 2019 maximum of 28 µg/L (October). Since then, TCE concentrations have decreased to a 2021 maximum of 18 µg/L (October). During 2021, only one well in the 854-DIS area contained VOCs other than TCE; extraction well W-854-2139 contained 0.5 µg/L of *cis*-1,2 DCE (January, April), which is below the MCL cleanup standard of 6 µg/L.

In the Building 858 Drop Tower area, VOC concentrations in groundwater remained below their respective reporting limits during the reporting period.

$Tnbs_1/Tnsc_0$ HSU Soil Vapor

General trends of TVOC concentrations in soil vapor in the $Tnbs_1/Tnsc_0$ HSU:

- The historical maximum TVOC concentration was 4.4 $ppm_{v/v}$ in vapor extraction well W-854-1834 (November 2005).
- TVOC concentrations decreased to a current maximum of 0.15 $ppm_{v/v}$ (entirely TCE) in well W-854-1834 (January).
- TVOC concentrations have remained below 0.5 $ppm_{v/v}$ since 2008 both during operating conditions and in rebound samples.

The historical maximum TVOC concentration in soil vapor in the Building 854 source area (4.4 $ppm_{v/v}$, November 2005) was in 854-SRC SVTS extraction well W-854-1834 and was comprised entirely of TCE; this was representative of conditions during normal vapor extraction operations. After operation of 854-SRC SVTS began in 2007, TCE concentrations declined to less than 0.5 $ppm_{v/v}$ by 2008 and have remained below 0.5 $ppm_{v/v}$ both during operation of the facility and during shutdown periods to evaluate potential rebound in concentrations. The 2021 maximum TCE vapor concentration in this well was 0.15 $ppm_{v/v}$ (January). TCE concentrations in vapor at this location are diffusion-limited. The continual, but slow, decrease in concentrations indicates progress in remediation of VOCs in this area. Although concentrations are low, well W 854-1834 produces a high volume of soil vapor and removes a significant mass of VOCs. Because of the significant mass removal and low operations and maintenance costs, DOE/LLNL has continued to operate this SVTS, but periodically evaluates its effectiveness in relation to shutdown criteria. At present, DOE/LLNL plans to continue to extract and treat vapor from the well. If, in the future a recommendation is made to curtail this activity, the regulatory agencies would be consulted for concurrence.

2.6.3.2.2. Perchlorate Concentrations and Distribution

Qls/Tnbs$_1$ HSU

During 2021, perchlorate concentrations only exceeded the 4 µg/L reporting limit in one well screened in the Qls/Tnbs$_1$ HSU or perched Tnbs$_1$ water-bearing zones; perchlorate was detected in monitor well W-845-05 (4.1 µg/L, November). There have been two other detections of perchlorate in this well in the past, in 2001 (4.1µg/L) and in 2014 (4.4µg/L).

Tnbs$_1$/Tnsc$_0$ HSU

General trends of perchlorate concentrations in groundwater in the Tnbs$_1$/Tnsc$_0$ HSU:

- The historical maximum perchlorate concentration is 27 µg/L in monitor well W-854-1823 (March 2003); concentrations at this location have been slowly declining to a 2021 maximum of 20 µg/L (April).
- The current maximum perchlorate concentration is 30 µg/L in monitor well W-854-3308 (March); concentrations at this well have been generally increasing since initial well development in 2017.
- The 2021 spatial distribution of perchlorate above the 4 µg/L reporting limit remains very similar to the 2020 distribution.
- The distribution and concentrations of perchlorate in Tnbs$_1$/Tnsc$_0$ HSU groundwater during the reporting period are generally similar to those of recent years, with the exception of a few wells (W-854-1823, W-854-3308, and W-854-3309) that have shown a consistent increase in concentrations, as described below.

In the 854-SRC area, extraction well W-854-02 has historically contained perchlorate in groundwater above the 6 µg/L MCL cleanup standard, with concentrations typically ranging between 4.9 and 7.2 µg/L. The 2021 maximum perchlorate concentration at well W-854-02 was 5.7 µg/L (April). During 2021, perchlorate was detected in well W-854-08 at a concentration of 5.3 µg/L (December). Well W-854-08 occasionally does not contain enough water to sample due to water levels being near the screen bottom, and water levels are continuously dropping due to prolonged drought conditions. Thus, the recent samples collected may be lower in concentration and not be fully representative of the local perchlorate plume. A deeper $Tnbs_1/Tnsc_0$ HSU monitor well near well W-854-08 is planned for installation in the near future. The proposed well will be screened deeper to better monitor remediation performance in this HSU when water levels drop below the screened interval at well W-854-08.

During operation of 854-PRX, perchlorate concentrations at well W-854-03 declined to below the 4 µg/L reporting limit in 2015 after engineering upgrades facilitated higher extraction rates from this well. When well W-854-03 is pumping, perchlorate concentrations in this well decrease to below the 4 µg/L reporting limit. However, concentrations have been higher recently under non-operating conditions (7.6 µg/L, August 2020). Operation during 2021 illustrates this behavior; continuous pumping began at well W-854-03 in December 2020 and perchlorate concentrations decreased from 6.2 µg/L (January) to below the 4 µg/L reporting limit (April) and remained below the recent 2 µg/L to 4 µg/L reporting limit for the remainder of 2021. Because perchlorate concentrations at nearby performance monitor well W-854 3405 have been consistent, ranging from 5.8 µg/L (February 2019) to 7.4 µg/L (November 2018), with a 2021 maximum of 9.8 µg/L (September), it is likely that well W-854-03 is extracting water from fractures with multiple flow regimes. It appears that well W-854-03 is capturing clean water in addition to perchlorate-bearing groundwater, effectively diluting perchlorate concentrations to below reporting limits when it is pumping and extracting groundwater.

Immediately downgradient of 854-PRX, perchlorate concentrations in $Tnbs_1/Tnsc_0$ HSU groundwater have remained high in monitor well W-854-3308, with a 2021 maximum concentration of 30 µg/L (April). Perchlorate concentrations in other nearby wells completed in this HSU ranged from 14 µg/L (well W-854-3309, March) to 26 µg/L (well W-854-3309, November). Perchlorate concentrations at wells W-854-3308 and W-854-3309, which are new monitor wells near well W-854-1823, have been increasing since initial well development in 2017. Perchlorate concentrations in well W-854-3308 increased from below the 4 µg/L reporting (August 2017) to 30 µg/L (April 2021). Concentrations in well W-854-3309 increased from 7.9 µg/L (September 2017) to 26 µg/L (November 2021).

At 854-DIS, except for one unusually high concentration in the July 2017 sample from extraction well W-854-2139 (14 µg/L), perchlorate concentrations have typically ranged from below reporting limits to a maximum of 7.1 µg/L (June 2019). Concentrations remained within that range during 2021, with a maximum perchlorate concentration of 5.7 µg/L in well W-854-07 (May). Extraction well W-854-2139, located near decommissioned water-supply Well 13, is the sole groundwater extraction well for 854-DIS. The 2021 maximum perchlorate concentration in W-854-2139 was 4.6 µg/L (April).

In the Building 858 Drop Tower area, during the previous ten years, perchlorate concentrations in well W-854-45 have ranged from 8.1 µg/L to 15 µg/L. The 2021 maximum in the Building 858 Drop

Tower area was 13 µg/L (April) in well W-854-3307, similar to the 2020 maximum of 12 µg/L in the same well.

2.6.3.2.3. Nitrate Concentrations and Distribution

Qls/Tnbs$_1$ HSU

General trends of nitrate concentrations in groundwater in the Qls/Tnbs$_1$ HSU:

- The maximum nitrate concentrations in this HSU typically occur in well W-854-14, near the Building 858 Drop Tower, where nitrate concentrations have historically ranged from 130 mg/L to 270 mg/L since 2001, with a decline to a 2021 maximum nitrate concentration of 80 mg/L (April).
- During 2021, other Qls/Tnbs$_1$ HSU wells contained 8.6 mg/L to 51 mg/L of nitrate, with no apparent spatial trend.

During 2021, nitrate concentrations ranging from 8.6 mg/L (well W-854-15, April) to 51 mg/L (well W-854-05, April) were present in the Qls/Tnbs$_1$ HSU in the 854-SRC and 854-PRX areas, slightly exceeding the 45 mg/L MCL cleanup standard. Concentrations in this area are relatively stable, with no apparent spatial trend.

Nitrate is also present in the Building 854 Drop Tower area. In this area, the maximum concentrations are typically found in well W-854-14, where nitrate has historically ranged from 130 mg/L to 270 mg/L since 2001, with a decline to a 2021 maximum of 80 mg/L (April).

Tnbs$_1$/Tnsc$_0$ HSU

General trends of nitrate concentrations in groundwater in the Tnbs$_1$/Tnsc$_0$ HSU:

- The historical maximum nitrate concentration was 180 mg/L in monitor well W-854-08 (September 1996); however, since 2002, nitrate concentrations in the well have ranged from 31 mg/L to 53 mg/L.
- Nitrate concentration trends remained stable during 2021, with no changes to spatial distribution.
- The 2021 spatial distribution of nitrate concentrations above the 45 mg/L MCL cleanup standard remains very similar to the 2020 distribution.

In the 854-SRC area, five wells contained nitrate near or above the 45 mg/L cleanup standard (W-854-02, W-854-08, W-854-18A, W-854-2218, and W-854-2611), with a 2021 maximum of 59 mg/L in well W-854-02 (July).

In the 854-PRX area, nitrate concentrations in extraction well W-854-03 have remained below the 45 mg/L MCL cleanup standard since 2010, including 2021, with a maximum nitrate concentration of 42 mg/L (January and May). Concentrations in nearby monitor well W-854-3405 were higher, with a 2021 maximum of 70 mg/L (April). Concentrations in downgradient wells W-854-1823, W-854-3308, and W-854-3309 remained below the MCL, with a 2021 maximum of 29 mg/L (well W-854-1823, April).

In the 854-DIS area, nitrate concentrations remain below the 45 mg/L MCL cleanup standard, with a 2021 maximum of 26 mg/L in monitor well W-854-07 (May).

At the Building 858 Drop Tower area, the 2021 maximum nitrate concentration in the Tnbs$_1$/Tnsc$_0$ HSU was 62 mg/L (W-854-45, November). Nitrate concentrations in well W-854-45 have shown a

steadily increasing trend from 2004 (16 mg/L) to present. There are no other $Tnbs_1/Tnsc_0$ HSU wells in this area with sufficiently long histories to compare nitrate concentration trends. Wells W-854-3306 and W-854-3307 contained nitrate above the 45 mg/L MCL cleanup standard also, with 57 mg/L (April) and 54 mg/L (April), respectively. The third well installed in the area in 2017, W-854-3305, contained nitrate at a concentration of 3.8 mg/L (April).

2.6.3.3. Building 854 OU Remediation Optimization Evaluation

The 854-SRC GWTS was secured from January 1 until April 6 for freeze protection and was shut down for several days on four occasions in 2021 due to power outages or control system issues (Table 2.5). The facility was secured again for freeze protection on November 16. During 2021, approximately 1.38 million gal of groundwater were extracted from the 854-SRC GWTS. During the 2021, the GWTS removed 111 g of VOCs, 5.5 g of perchlorate, and 244 kg of nitrate from extracted groundwater. Both the volume treated, and contaminant mass removed were representative of past reporting periods, and 14-30% increases from 2020, when facility run time was affected due to pandemic-related limits on personnel availability.

Similar to the GWTS, the 854-SRC SVTS was shut down for several days on four occasions in 2021 due to power outages or control system issues (Table 2.5). The facility was also secured from August 11 to August 17 due to treatment media changeout. The SVTS extracted approximately 18.3 million cubic ft of soil vapor and removed 366 g of VOC mass, representing a 30% increase in run time and mass removed over 2020, when facility run time was affected due to pandemic-related limits on personnel availability. Despite consistently low VOC vapor concentrations, substantial VOC mass continues to be removed from the source area due to relatively high vapor flow rates (approximately 34 scfm). This VOC mass is volatilizing from residual TCE in the vadose zone beneath the Building 854 source area and from the dissolved VOC plume in $Tnbs_1/Tnsc_0$ HSU groundwater beneath the SVE well.

The 854-PRX GWTS was secured from May 6 to May 10 and between May 21 to May 24 during power outages but ran consistently otherwise (Table 2.5). During 2021, approximately 1.53 million gal of groundwater were extracted from the 854-PRX GWTS, a significant increase from 2020 (399,000 gal), when the facility had very low operational uptime due to pump issues and pandemic-related limitations on personnel availability. During 2021, 32 g of VOCs, 9.3 g of perchlorate, and 232 kg of nitrate were removed from extracted groundwater (Table Summ-1). The mass of perchlorate removed from extracted groundwater varies from semester to semester, and the calculation is affected by the sampling date relative to the recent pumping history of the extraction well. When extraction well W-854-03 is not operating, perchlorate concentrations are approximately 6 to 7 µg/L. After pumping for several days or weeks, the well appears to begin extracting cleaner water, effectively diluting perchlorate concentrations to below the reporting limit and resulting in calculations of "zero" mass removed. In 2015, this perceived "dilution" began to have a noticeable effect on mass removal estimates when the facility was upgraded from the bio-treatment units, which were only capable of treating extracted water at rates below 1.5 gpm. The current 854-PRX facility treats extracted water at a rate of 3 gpm.

During 2021, operational efficiency at the 854-DIS GWES was seriously degraded by a failing control system resulting in very low volumes of extracted water. To correct this, the facility was secured on June 24 through the remainder of the reporting period pending planned engineering

upgrades to the control and data collection systems (Table 2.5). During 2021, the system extracted an average of less than 20 gal of water per month and effectively removed no VOC, perchlorate, or nitrate mass. The controls system upgrades to rectify these performance issues commenced implementation during the second semester of 2021.

2.6.3.4. Building 854 OU Remedy Performance Issues

There were no new issues that affected the performance of the cleanup remedy for the Building 854 OU.

Perchlorate concentrations remain above the 6 µg/L MCL cleanup standard in several areas of the Building 854 OU. A work plan is being developed for enhanced *in situ* bioremediation treatability testing at one or more sub-areas in the Building 854 OU. An electron donor (most likely ethyl lactate) would be mixed with groundwater or treated effluent and injected to biotically reduce perchlorate concentrations. The work plan will be submitted for regulatory review.

The overall remedy at the Building 854 OU continues to be effective and protective of human health and the environment, and to make progress toward cleanup.

2.7. Building 832 Canyon (OU 7)

Starting in the late 1950s and early 1960s, and until 1985, facilities in the Building 830 and Building 832 areas were used to test the stability of weapon components under various environmental conditions. Contaminants were released from Buildings 830 and 832 through piping leaks and surface spills during testing activities at these buildings.

Three GWTSs are currently operated in the Building 832 Canyon OU: 832-SRC, 830-SRC, and 830-DISS. Additionally, two SVTSs are currently operated at the 832-SRC and 830-SRC areas. A map of the Building 832 Canyon OU showing the locations of monitor and extraction wells and treatment facilities is presented on Figure 2.7-1.

The 832-SRC GWTS removes VOCs, perchlorate, and nitrate from groundwater, and the SVTS removes VOC mass from soil vapor. The GWTS and SVTS began operation in September and October 1999, respectively. During 2021, groundwater was extracted from wells W-832-01, W-832-3020, W-832-10, and W-832-25. Groundwater and soil vapor were extracted from wells W-832-12 and W-832-15. When brought online again in 2022 under full operation, long-term average total flow rates from all wells are expected to be less than 0.5 gpm for groundwater and 3.8 scfm for soil vapor. The current GWTS configuration includes two ion-exchange resin columns connected in series to remove perchlorate and three aqueous-phase GAC vessels (also connected in series) to remove VOCs. Nitrate-bearing treated effluent is then discharged via a misting tower on to the landscape for uptake and utilization of the nitrate by indigenous grasses. A positive displacement rotary lobe blower is used to create a vacuum at selected wellheads through a system of piping manifolds. The contaminated vapors are treated using three vapor-phase GAC vessels connected in series. Treated soil vapors are then discharged to the atmosphere under a permit issued by the SJVAPCD. Both the 832-SRC GWTS and SVTS were shut down for upgrades during most of the reporting period. The 832-SRC SVTS operated periodically for testing through 2021, and both the 832-SRC SVTS and GTWS were fully operational from October 19 until November 22, when they were secured for freeze protection. Both facilities are expected to be brought to full operation again in 2022 following cessation of freeze protection. The upgrades included connecting well W-832-3019 as a dual extraction well and

well W-832-3020 as a groundwater extraction well (to replace well W-832-11), as well as other engineering upgrades to the wellheads and data collection capabilities at associated extraction wells.

The 830-SRC GWTS removes VOCs, perchlorate, and nitrate from groundwater, and the SVTS removes VOCs from soil vapor. The GWTS and SVTS began operation in February and May 2003, respectively. The current system, which was redesigned in 2014 and restarted operations during the second semester of 2015, includes two ion-exchange resin columns connected in series to remove perchlorate and three aqueous-phase GAC vessels connected in series to remove VOCs. Groundwater is extracted from wells W-830-19, W-830-57, W-830-59, W-830-60, W-830-2214, W-830-2215, and W-830-2701. Both groundwater and soil vapor are extracted from wells W-830-49 and W-830-1807, which operate as dual extraction wells. When operating, these nine wells extract groundwater at a combined flow rate of approximately 11 gpm. A manifold located between the ion-exchange resin columns and the GAC vessels enables non-perchlorate-bearing influent to bypass perchlorate treatment. Nitrate-bearing treated effluent is then discharged via a misting tower onto the landscape for uptake and utilization of the nitrate by indigenous grasses. The SVTS operates by creating a vacuum using a liquid-ring pump, which is connected to two dual extraction wells (W-830-1807 and W-830-49). The two dual extraction wells also extract soil vapor at a combined flow rate of approximately 10 to 14 scfm. The VOC-bearing vapors are treated using three vapor-phase GAC vessels connected in series. Treated soil vapor is discharged to the atmosphere under a permit issued by the SJVAPCD.

The 830-DISS GWTS began operation in 2000, removing VOCs, perchlorate, and nitrate from groundwater. When the 830-DISS GWTS is operational, groundwater is extracted from wells W-830-51, W-830-52, and W-830-53 (relying on natural artesian pressure) at a flow rate of <1gpm, and also from W-830-2216 (using a pump), for a combined flow rate of approximately 2 to 3 gpm. When operating, extracted groundwater flows through ion-exchange columns to remove perchlorate at the 830-DISS location and the groundwater is piped to the CGSA GWTS for VOC removal. Nitrate-bearing treated effluent from the CGSA is then discharged via a misting tower onto the landscape for uptake and utilization of the nitrate by indigenous grasses.

2.7.1. Building 832 Canyon OU Groundwater and Soil Vapor Extraction and Treatment System Operations and Monitoring

2.7.1.1. Building 832 Canyon OU Compliance Summary

The 832-SRC SVTS operated periodically for testing during 2021 but was online for full operations from October 19 to November 22, operating in compliance with the SJVAPCD permit limitations. The 830-SRC GWTS and 830-SRC SVTS operated in compliance with RWQCB substantive requirements and with SJVAPCD permit limitations, respectively. The 830-DISS GWTS also operated in compliance with RWQCB substantive requirements during this reporting period.

The Building 832 Canyon OU treatment facility sampling and analysis plan complies with the monitoring requirements in the CMP/CP. The sampling and analysis plan for the first semester of 2022 is presented in Appendix B. No modifications were made to any of the plans during this reporting period.

2.7.1.2. Building 832 Canyon OU Operations and Maintenance Issues

Information concerning Building 832 Canyon facilities operations and maintenance issues is presented in Table 2.5.

2.7.1.3. Building 832 Canyon OU Facility Performance Assessment

The monthly groundwater and soil vapor discharge volumes and operational hours for the second semester of 2021 are summarized in Table 2.2. The total volume of groundwater and vapor extracted and treated, and mass removed during the reporting period are presented in Table Summ-1. The cumulative volume of groundwater and soil vapor treated and discharged, and mass removed are summarized in Table Summ-2. Analytical results for influent and effluent samples collected during the second semester of 2021 are presented in Table 2.4. The pH measurements are presented in Appendix A.

2.7.1.4. Building 832 Canyon OU Treatment Facility and Extraction Wellfield Modifications

The Building 832-SRC GWTS and SVTS were off-line for most of the reporting period to complete the construction upgrade project and perform testing and verifications of operational systems. Upgrades to the treatment facility have included improving instrumentation to the current design standard, which has enabled this facility to be integrated into the existing telemetry data acquisition system. New treatment media vessels for groundwater and vapor-phase GAC, and perchlorate ion-exchange media vessels and associated pipelines have been installed. All extraction wellheads and down-well instrumentation have been updated to the current standard. The wellfield modifications include the addition of two new extraction wells to the facility, W-832-3020 (to replace extraction well W-832-11) and a new dual extraction well W-832-3019. The 832-SRC SVTS operated periodically for testing through 2021, and both the 832-SRC SVTS and GTWS were fully operational from October 19 until November 22, when they were secured for freeze protection. Both facilities are expected to be brought to full operation again in 2022 following the cessation of freeze protection.

During 2021, the misting towers were used to discharge treated groundwater. DOE/LLNL continues to evaluate long-term alternatives for the final disposition of treated effluent. These options include potential injection into existing wells or continuation of misting. Until a final decision is made, groundwater will be discharged at the misting towers, as described above. Any proposed changes in the method for discharge of treated effluent will be presented to the regulatory agencies for concurrence. No treatment facility modifications were made at the 830-SRC GWTS and SVTS, or the 830-DISS GWTS during 2021.

2.7.2. Building 832 Canyon OU Groundwater and Surface Water Monitoring

The sampling and analysis plan for groundwater and surface water monitoring for the entire year is presented in Appendix C. This table explains deviations from the sampling plan and indicates any additions made to the CMP.

During the second semester of 2021, groundwater monitoring was conducted in accordance with the CMP monitoring requirements with the following exceptions:

- A total of 15 analyses from 11 different wells were not performed because the wells were dry, or there was insufficient water for sample collection.

- A total of one analyses for one well was not performed because of inoperable equipment; this pump will be repaired in 2022.
- Samples for a total of 30 analyses from 10 different wells were collected, but due to analytical laboratory issues, were not performed. DOE/LLNL was not able to re-sample for these analyses.
- A total of 33 analyses for 33 different wells were not performed due to limited personnel availability due to COVID-19 pandemic related issues.

Analytical results and groundwater elevation measurements obtained during 2021 are presented in Attachment 1 and Appendix D, respectively.

Groundwater elevations and flow directions for the Qal/WBR HSU are presented on Figure 2.7-2. Groundwater elevation contour maps including hydraulic capture zones for the $Tnsc_{1ab}$ and Upper $Tnbs_1$ HSUs are presented on Figures 2.7-3 and 2.7-4, respectively.

2.7.3. Building 832 Canyon OU Remediation Progress Analysis

2.7.3.1. Building 832 Canyon OU Mass Removal

The monthly groundwater and soil vapor contaminant mass removal estimates for the second semester of 2021 are summarized in Table 2.3. The total masses removed during the reporting period and cumulative mass estimates are summarized in Table Summ-1 and Table Summ-2, respectively.

2.7.3.2. Building 832 Canyon OU Contaminant Concentrations and Distribution

At the Building 832 Canyon OU, VOCs (mostly TCE) are the primary COCs detected in groundwater. Perchlorate and nitrate are the secondary COCs. These constituents have been detected primarily in the Qal/WBR and $Tnsc_{1ab}$ HSUs. VOCs and perchlorate have also been detected at relatively low concentrations in the $Tnbs_2$ and Upper $Tnbs_1$ HSUs.

A map showing individual VOC concentrations for the Qal/WBR HSU is shown on Figure 2.7-5. A total VOC isoconcentration contour map and individual VOC concentrations for the $Tnsc_{1ab}$ and Upper $Tnbs_1$ HSUs are presented on Figures 2.7-6 and 2.7-7, respectively. A map showing perchlorate concentrations for the Qal/WBR HSU is shown on Figure 2.7-8. A perchlorate isoconcentration contour map for the $Tnsc_{1ab}$ HSU is presented on Figure 2.7-9. Maps showing nitrate concentrations for the Qal/WBR and $Tnsc_{1ab}$ HSUs are presented on Figures 2.7-10 and 2.7-11, respectively.

2.7.3.2.1. VOC Concentrations and Distribution

TCE is the primary VOC detected in Building 832 area groundwater. During 2021, VOCs other than TCE present above reporting limits in the Building 832 source area were *cis*-1,2-DCE; CFORM; Freon 11; chloroethane; and methylene chloride. Of these VOCs, only TCE and *cis*-1,2-DCE were present in the Building 832 area at concentrations above their MCL cleanup standards of 5 µg/L and 6 µg/L, respectively.

TCE was the primary VOC detected in Building 830 area groundwater, including the 830-SRC and 830-DISS areas. During 2021, the other VOCs present above reporting limits in the Building 830 area were PCE; *cis*-1,2-DCE; *trans*-1,2-DCE; CFORM; 1,2-DCA; and Freon 11. Of these VOCs, only TCE and 1,2-DCA were detected at concentrations above their MCL cleanup standard of 5 µg/L and 0.5 µg/L, respectively. VOC concentrations and distribution are discussed by HSU below.

Qal/WBR HSU

General trends of groundwater VOC concentrations in the Qal/WBR HSU:

- The historical maximum groundwater TVOC concentration is 10,000 µg/L in 2003 in 830-SRC monitor well SVI-830-035.
- TVOC concentration in groundwater decreased to a current maximum of 480 µg/L in March 2021 in the same well.
- VOC groundwater concentrations in the Qal/WBR HSU increased slightly in a few wells, but generally remained stable or decreased slightly from 2020 to the second semester of 2021. The 2021 spatial distribution of VOC concentrations remains very similar to the 2020 distribution.

Since remediation began in 1999 in the Building 832 source area, groundwater TVOC concentrations in wells screened in the Qal/WBR HSU have decreased from a historical maximum of 1,800 µg/L in 1998 (well W-832-18) to a 2021 maximum of 160 µg/L (well W-832-23, September).

The highest VOC concentrations in the Qal/WBR HSU in the Building 832 Canyon OU are found in the 830-SRC area, where remediation began in 2000. Here, concentrations have decreased from a historical maximum of 10,000 µg/L in 2003 in monitor well SVI-830-035 to a 2021 maximum of 480 µg/L (SVI-830-052, March).

In the 830-DISS area during 2021, TCE was the only VOC present in groundwater in the Qal/WBR HSU. Concentrations of TCE in groundwater ranged from below the detection limit in guard well W-880-02 (March, May) to 14 µg/L at well W-832-3017 (February). In the 830-DISS area, between 2011 and 2018, VOC concentrations in the Qal/WBR area had remained below their respective MCL cleanup standards. However, from 2018 through March 2021, concentrations increased to a range of 7.6 µg/L (March 2021) to 15 µg/L (March 2018). Wells that exhibited these increases have begun to show decreases in concentration. TVOC concentrations at Spring 3 decreased from a 2018 high of 15 µg/L to a 2021 maximum of 7.6 µg/L (March, all TCE), and continued to decrease further to 1.8 µg/L in August 2021. At well W-832-SC3, concentrations decreased from a 2018 maximum of 15.5 µg/L (March) to a 2021 maximum of 4.5 µg/L (March). The recent increases in VOC concentrations in the area may be related to the suspension of operation of 830-DISS to accommodate engineering upgrades at CGSA-GWTS and the frequent securing of the upgradient facility 830-SRC GWTS during the past few years for modifications. These facilities were both operational during 2021.

During 2021, VOCs were not detected above reporting limits in Qal/WBR HSU guard well W-880-02, located south of the 830-DISS area near the Site 300 southern boundary.

$Tnbs_2$ HSU

General trends of groundwater VOC concentrations in the $Tnbs_2$ HSU:

- The historical maximum groundwater TVOC concentration is 20 µg/L in 2007 in extraction well W-830-2216.
- TVOCs in groundwater decreased to a current maximum of 4.7 µg/L in March 2021 in the same well.

Well W-830-2216 has been extracting groundwater from the $Tnbs_2$ HSU since 2007. The presence of COCs in this well is likely due to releases from several source areas in the HEPA and Building 832 Canyon OUs. While the $Tnbs_2$ HSU wells are technically located within the bounds of the Building 832 Canyon OU, the performance of these wells is discussed in more detail in the HEPA OU section. The

bounds of the HEPA OU overlap the Building 832 Canyon OU in this area. Also, the discussion of the performance of the remedy for the entire $Tnbs_2$ HSU is presented in the HEPA OU section, rather than being split up and partially discussed in detail here.

$Tnsc_{1ab}$ HSU

General trends of groundwater VOC concentrations in the $Tnsc_{1ab}$ HSU:

- The historical maximum groundwater TVOC concentration is 13,000 µg/L in 2003 in well W-830-49.
- TVOCs in groundwater decreased to a current maximum concentration of 1,800 µg/L in extraction well W-830-49 and W-830-19 (April 2021).
- VOC concentration trends in the $Tnsc_{1ab}$ HSU remained stable or decreased slightly in individual wells during 2021. The 2021 spatial distribution of VOC concentrations remain very similar to the 2020 distribution.

The highest VOC concentrations in the $Tnsc_{1ab}$ HSU are found in the 830-SRC area, where remediation began in 2000. New monitor well W-830-3601 did not yield VOCs above the reporting limit in any samples collected since its installation in September 2020 until the second semester of 2021; TCE and *cis*-1,2 DCE were detected in September (1.1 µg/L µg/L TCE and 0.73 µg/L *cis*-1,2 DCE) and again in November (1.7 µg/L TCE and 0.76 µg/L *cis*-1,2 DCE), still below the reporting limits of 5 µg/L and 6 µg/L, respectively. This well is located to the west of the 830-SRC area and helps to constrain the $Tnsc_{1ab}$ VOC plume along its western edge between monitor wells W-832-3304 and W-830-2806, where VOCs have never been detected.

Since remediation of the $Tnsc_{1ab}$ HSU began in 2000, TVOC concentrations in groundwater at the Building 832-SRC area have generally decreased from the historical maximum of 1,700 µg/L in 1998 (monitor well W-830-27). However, with the installation of well W-832-3019 in 2015, TVOC concentrations have ranged from 110 µg/L (April 2021) to 1,900 µg/L (August 2016), the historical maximum for TVOCs in 832-SRC area groundwater. The 2021 maximum TVOC concentration at well W-832-3019 was 940 µg/L (March). Well W-832-3019 has been connected to the 832-SRC GWTS and SVTS as a dual extraction well as part of the operational maintenance and engineering upgrades recently completed at this location. The 832-SRC GWTS was brought back online briefly during the second semester of 2021 before freeze protection was necessary. Concentrations of TVOCs measured in other 832-SRC area $Tnsc_{1ab}$ HSU wells during the reporting period were generally similar to concentrations from recent reporting periods. At new monitor well W-832-3603, completed during the second semester of 2020, VOCs have not been detected above reporting limits in any of the six samples collected from the well since installation, including the four quarterly samples in 2021. This well is located southeast of the 832-SRC area, where there are no nearby wells, and provides necessary data to delineate the eastern edge of the $Tnsc_{1ab}$ VOC plume. In past years The VOC plume has been represented conservatively as extending farther east due to lack of constraining data points. Analytical data from this well will continue to be monitored closely.

In the 830-DISS area, TVOC concentrations in $Tnsc_{1ab}$ HSU wells have decreased from a historical maximum of 170 µg/L (extraction well W-830-52, 2002) to a 2021 maximum of 30 µg/L in monitor wells W-830-2311 (March) and W-830-51 (October). Farther south along Building 832 Canyon, the leading edge of the $Tnsc_{1ab}$ VOC plume continues to be contained within the Site 300 boundary, based

on TVOC concentrations below the individual 0.5 µg/L reporting limits in guard wells W-880-03, W-830-1730, and W-4C.

Upper $Tnbs_1$ HSU

General trends of groundwater VOC concentrations in the Upper $Tnbs_1$ HSU:

- The historical maximum groundwater TVOC concentration is 100 µg/L in 1998 in well W-830-28.
- TVOC concentrations in groundwater decreased to a current maximum of 26 µg/L in July 2021 in extraction well W-830-2215.
- VOC concentration trends in the Upper $Tnbs_1$ HSU increased slightly in a few wells, but generally remained stable or decreased slightly from 2020 to 2021; the 2021 spatial distribution of VOC concentrations remain very similar to the 2020 distribution.

New Upper $Tnbs_1$ HSU monitor well, W-832-3602, was completed in August 2020. The well is located north of the other Upper $Tnbs_1$ monitor wells, close to the HSU's northernmost extent of saturation. Concentrations of TVOCs at this well in 2021 ranged from 8.2 µg/L (September) to 14 µg/L (May and October). These concentrations are consistent with the hydrogeological conceptual model for this area. While the extent of VOC concentrations above 10 µg/L has previously been represented in plume maps as terminating south of monitor well W-832-2906, the VOC plume has been represented as extending north past the saturated extent of the Upper $Tnbs_1$ HSU since W-832-2906 was completed in 2013. VOC concentrations in new monitor well W-832-3602 will continue to be monitored closely.

At the Building 830-SRC area, monitor well W-830-18, which serves as the performance monitor well for extraction well W-830-2215, exhibited an increasing TVOC trend while well W-830-2215 was extracting groundwater from 2006 through 2013; VOC concentrations have remained relatively stable since then, through 2021. TVOC concentrations at the adjacent extraction well W-830-2215 have slightly increased from 2015, ranging from 15 µg/L (2015) to 29 µg/L (2018). This distribution indicates that the extraction well is again capturing the highest VOC concentrations in the area after having been idle for much of 2015 and 2016 to accommodate engineering upgrades and modifications.

In the downgradient area of the Upper $Tnbs_1$ HSU, VOC concentrations have not exceeded their reporting limits in guard wells W-830-15 and W-832-2112 since the wells were installed in 1995 and 2005, respectively.

Lower $Tnbs_1$ HSU

During 2021, in the Building 832 Canyon OU, VOCs have not been detected above reporting limits in any wells screened within the Lower $Tnbs_1$ HSU. Historically, the only Lower $Tnbs_1$ HSU well where VOCs have been detected in the Building 832 Canyon OU is W-830-29, with a historical maximum TVOC concentration of 1.8 µg/L in June 1999. However, VOCs have not been detected in this well above reporting limits since August 2009. No other Lower $Tnbs_1$ HSU wells in the 832 Canyon OU have historically yielded VOCs in excess of reporting limits in any samples.

2.7.3.2.2. VOC Concentration and Distribution in Soil Vapor

Qal/WBR and $Tnsc_{1ab}$ HSUs

Currently, in the Building 832 Canyon OU, there are five vapor extraction wells. In the 832-SRC area, wells W-832-12 and W-832-15 are completed in the Qal/WBR HSU and well W-832-3019 is

completed in the $Tnsc_{1ab}$ HSU. In the 830-SRC area, well W-830-1807 is completed in the Qal/WBR HSU and well W-830-49 is completed in the $Tnsc_{1ab}$ HSU. Because of the close relationship between the $Tnsc_{1ab}$ and Qal/WBR HSUs, the VOC concentrations and distribution for both HSUs are described together.

General trends of soil vapor VOC concentrations in the Qal/WBR and $Tnsc_{1ab}$ HSUs:

- The only VOC detected above reporting limits in soil vapor during 2021 was TCE.
- The historical maximum soil vapor TVOC concentration is 259 $ppm_{v/v}$ in 2007 in dual extraction well W-830-49.
- Excluding well W-832-3019, TVOCs in soil vapor decreased to a current maximum of 4.7 $ppm_{v/v\ in}$ in W-830-49 (July).
- Soil vapor concentrations in wells W-832-12 and W-832-15 have not yielded concentrations above 0.76 $ppm_{v/v}$ since 2011, including during rebound tests.
- Soil vapor concentrations in new dual extraction well W-832-3019 rose to a 2021 maximum of 140 $ppm_{v/v}$ (September) and decreased to 64 $ppm_{v/v}$ (October) after the facility became operational.
- Soil vapor concentrations in wells W-832-12 and W-832-15 have not yielded concentrations above 0.76 $ppm_{v/v}$ since 2011, including during rebound tests.
- Excluding W-832-3019, VOC soil vapor concentration trends remained stable or decreased slightly in individual wells from 2020 through the 2021; the 2021 spatial distribution of VOC concentrations remains very similar to the 2020 distribution.

Soil vapor samples are typically collected every six months from 832-SRC dual extraction wells W-832-12, W-832-15, and newly connected extraction well W-832-3019 while non-operational; the frequency will increase when soil vapor extraction resumes after freeze protection ceases in 2022. Concentrations increased dramatically in recent samples from well W-832-3019 ranging from 5.1 $ppm_{v/v}$ (April) to 140 $ppm_{v/v}$ (September). Dual extraction well W-832-3019 was connected to the 832-SRC SVTS and GWTS during the second semester of 2020. Testing and verification of the system were completed periodically through 2021, and the well began full-time extraction on October 19. Because of the high soil vapor and groundwater concentrations, analytical results from well W-832-3019 are monitored closely. Including results of rebound testing, since 2011, neither well W-832-15 nor well W-832-12 have yielded TVOC concentrations greater than 0.76 $ppm_{v/v}$. During 2021, soil vapor samples from wells W-832-12 and W-832-15 yielded maximum VOC concentrations of 0.57 $ppm_{v/v}$ and 0.75 $ppm_{v/v}$, respectively (all TCE).

Soil vapor samples are also collected quarterly from 830-SRC area dual extraction wells W-830-49 and W-830-1807, and also after long periods of operational downtime. Concentrations in soil vapor in these two extraction wells are similar to those of recent reporting periods. During 2021, TVOC concentrations ranged from 0.26 $ppm_{v/v}$ (W-830-1807, March) to 4.7 $ppm_{v/v}$ (W-830-49, July).

2.7.3.2.3. HE Compound Concentrations and Distribution

Including 2020, HE compounds have never been detected in groundwater in any Building 832 Canyon OU well, although HMX is a COC in surface and subsurface soil in the Building 832 Canyon OU 832-SRC area.

2.7.3.2.4. Perchlorate Concentrations and Distribution

Qal/WBR HSU

General trends of perchlorate concentrations in the Qal/WBR HSU:

- The historical maximum perchlorate concentration is 51 µg/L in 1998 in monitor well W-830-13.
- Perchlorate concentrations decreased to a current maximum of 5.5 µg/L in February 2021 in monitor well W-830-13.
- Perchlorate is only detected above the typical 4 µg/L reporting limit in a few wells in the Qal/WBR HSU in the 832 Canyon OU; overall, perchlorate concentrations have been decreasing over time.

The only detections of perchlorate in the Qal/WBR HSU during the reporting period were in wells W-832-12, W-832-13 (832-SRC area), and W-832-3017 (830-DISS area) at 2021 maximum concentrations of 3.2 µg/L, 5.5 µg/L, and 4.4 µg/L, respectively. During 2021, perchlorate was not detected in this HSU above the reporting limit in the 830-DISS area Qal/WBR HSU guard wells W-35B-01 and W-880-02.

$Tnbs_2$ HSU

The perchlorate observed in the Building 832 Canyon area $Tnbs_2$ HSU wells represents an extension of the downgradient portion of the perchlorate plume originating in the HEPA OU. Generally, perchlorate concentrations in the $Tnbs_2$ HSU in the Building 832 Canyon OU have historically been below the typical 4 µg/L reporting limit, except for a few instances. During 2021, the reporting limit for perchlorate analyses was generally lowered to 2 µg/L. As such, there may be additional detections of perchlorate in excess of the lower reporting limit. For example, during 2021, extraction well W-830-2216 contained perchlorate above the new 2 µg/L reporting limit (3.9 µg/L, July). This well has had a few detections of perchlorate in the past, (4.1 µg/L, 2016; 4.2 µg/L, 2007)

$Tnsc_{1ab}$ HSU

General trends of perchlorate concentrations in the $Tnsc_{1ab}$ HSU:

- The historical maximum perchlorate concentration is 38 µg/L in 2017 in dual extraction well W-832-3019.
- Perchlorate concentrations decreased to a current maximum of 9.9 µg/L (July) in dual extraction well W-830-3019.
- Perchlorate concentration trends in the $Tnsc_{1ab}$ HSU remained stable in individual wells from 2019 through 2021; the current spatial distribution of perchlorate concentrations remain very similar to the 2020 distribution even with new detections due to the lowered reporting limit.

In the Building 830 and 832 source areas in the $Tnsc_{1ab}$ HSU (and the entire OU), the historical maximum perchlorate concentration of 38 µg/L was detected in well W-832-3019 in February 2017. Prior to this elevated concentration, perchlorate in well W-832-3019 had fluctuated between 8.3 µg/L and 18 µg/L. The perchlorate concentrations in samples taken later in 2017 (August and December) were both 13 µg/L, and the maximum 2018 perchlorate concentration in this well was also 13 µg/L.

The 2019, 2020, and 2021 maxima of 13 µg/L, 11 µg/L, and 10 µg/L, respectively, suggest that the 38 µg/L February 2017 result is atypical of perchlorate concentrations in this well. Baseline sampling at new monitor well W-830-3601 yielded 17 µg/L of perchlorate (October 2020). This well is located to the west of the 830-SRC area and helps to delineate the extent of the $Tnsc_{1ab}$ perchlorate plume along its western edge between monitor wells W-832-3304 and W-830-2806, where perchlorate has not been detected above reporting limits. Subsequent sampling of W-830-3601 during 2021 did not yield perchlorate above reporting limits. Perchlorate concentrations at this well will continue to be monitored closely.

In the 830-DISS area, perchlorate concentrations were below reporting limits except for artesian extraction wells W-830-51, W-830-52, and W-830-53, and nearby monitor well W-830-2311. The concentrations ranged from 4.1 to 5.4 µg/L and are comparable with previous data. This distribution is similar to that of previous reporting periods. Including 2021, perchlorate has never been detected in $Tnsc_{1ab}$ HSU guard wells W-830-1730 and W-4C.

Upper $Tnbs_1$ HSU

Including 2021, perchlorate concentrations in the Upper $Tnbs_1$ HSU have not exceeded the 4 µg/L reporting limit since 2005, except for likely analytical laboratory errors.

Lower $Tnbs_1$ HSU

Including 2021, perchlorate concentrations in the Lower $Tnbs_1$ HSU have not exceeded the 4 µg/L reporting limit.

2.7.3.2.5. Nitrate Concentrations and Distribution

During this reporting period, maximum nitrate concentrations in groundwater remained high both in the vicinity of the Building 832 and Building 830 source areas, and in the shallow Qal/WBR HSU; and low or below the 0.5 mg/L reporting limit in the downgradient, deeper parts of all Building 832 Canyon HSUs. Concentration trends in the various HSUs are discussed below. Spatial and temporal nitrate concentration trends in all HSUs in the 832 Canyon OU continue to support the interpretation that nitrate is naturally attenuating in the groundwater.

Qal/WBR HSU

General trends of nitrate concentrations in the Qal/WBR HSU:

- The historical maximum nitrate concentration is 240 mg/L in monitor well SVI-830-033 in 2008.
- Nitrate decreased to a current maximum of 180 mg/L in monitor well W-832-19 in March.

During 2021, concentrations of nitrate in wells screened in the Qal/WBR HSU in all areas ranged from a maximum of 180 mg/L in 832-SRC monitor well W-832-19 (March) to <1 mg/L in 830-DISS guard well W-880-02 (March). Generally, nitrate concentrations followed a decreasing trend downgradient from the 832-SRC area to the 830-DISS area.

During 2021, nitrate concentrations remained below 1 mg/L in guard wells W-35B-01 and W-880-02, which are located near the Site 300 boundary.

$Tnsc_{1ab}$ HSU

General trends of nitrate concentrations in the $Tnsc_{1ab}$ HSU:

- The historical maximum nitrate concentration is 440 mg/L in extraction well W-830-49 in 1998.
- Nitrate concentrations decreased to a current maximum of 180 mg/L in monitor well W-832-19 (March).

During 2021, nitrate concentrations in the $Tnsc_{1ab}$ HSU generally remained moderate to high, but stable (between a historical reporting limit of 1 mg/L and 180 mg/L), near the Buildings 830 and 832 source areas. The reporting limit for nitrate has varied over time from 0.1, 0.5, 1, and 4 mg/L. Nitrate continues to exhibit a significant decreasing concentration trend in the downgradient direction toward the Site 300 boundary, where confined hydraulic conditions conducive to *in situ* microbial denitrification exist. Since 2011, nitrate concentrations in downgradient $Tnsc_{1ab}$ guard wells W-830-1730 and W-4C were generally below the historical reporting limits of 0.1 and 0.5 mg/L and never exceeded 3.1 mg/L (W-830-1730, 2013), indicating that nitrate continues to naturally attenuate within the OU. Nitrate was not detected above the current 0.5 mg/L reporting limit in either new monitor well, W-830-3601 or W-832-3603, during baseline sampling events in 2020. However, in subsequent sampling during 2021, nitrate was detected in monitor well W-832-3603 in four quarterly samples below the 45 mg/L MCL, ranging from 3.5 mg/L (September) to 7 mg/L (March and May).

Upper $Tnbs_1$ HSU

General trends of nitrate concentrations in the Upper $Tnbs_1$ HSU:

- The historical maximum nitrate concentration is 27 mg/L in extraction well W-830-3408 in 2018.
- Nitrate decreased to a current maximum of 25 mg/L (February) in the same well.
- Nitrate concentrations in other Upper $Tnbs_1$ HSU locations were all below 14 mg/L.

During 2021, nitrate remained low in guard well W-830-15 with a maximum 2021 concentration of 6.2 mg/L (August). Nitrate concentrations at this location have varied from below reporting limits to a maximum of 8.7 mg/L (2004). At new monitor well W-832-3602, nitrate was detected at a concentration of 7.3 mg/L during baseline sampling in August 2020, and also in subsequent samples collected during 2021, with a maximum 2021 concentration of 14 mg/L (May), the highest concentration apart from well W-830-3408 (25 mg/L, February). These results are generally similar to the nitrate concentrations detected in nearby wells.

The very low nitrate concentrations in the downgradient areas and the absence of detectable nitrate in the southern site boundary guard wells are consistent with the interpretation that nitrate naturally attenuates due to *in situ* microbial denitrification in the Upper $Tnbs_1$ and other Neroly Formation bedrock HSUs.

Lower $Tnbs_1$ HSU

Including 2021, nitrate concentrations in the Lower $Tnbs_1$ HSU have not exceeded reporting limits (the highest historical reporting limit was 4 mg/L) since 1994, except for two instances. Well W-832-09 contained 44 mg/L of nitrate in a baseline sample (1994), which is likely a result of sampling error or poor well development; groundwater samples collected from this location since 1994 have not

exceeded reporting limits. Well W-830-29 also yielded 18 mg/L nitrate (2013); concentrations in the other samples collected from this location have not exceeded reporting limits.

2.7.3.3. Building 832 Canyon OU Remediation Optimization Evaluation

Despite the recent shutdown of several GWTSs and SVTSs, data indicate that overall, the remedy is making progress in preventing off-site plume migration, reducing source area concentrations, and removing contaminant mass. However, hydraulic capture remains difficult to assess in areas where wells cannot maintain continuous pumping. The low well yields result from a combination of geologic materials with low hydraulic conductivity and dewatering due to ongoing groundwater extraction amid limited recharge.

Qal/WBR HSU

In the Qal/WBR and $Tnsc_{1ab}$ HSUs, the extraction wellfields target the highest VOC plume concentrations emanating from the Building 832 and Building 830 source areas, but steep terrain and unstable canyon bottom soil conditions limit the availability of sites for new wells. In recent years, groundwater extraction has been further constrained by limited recharge and declining water levels in both source areas.

$Tnbs_2$ HSU

In the $Tnbs_2$ HSU in Building 832 Canyon, remediation continues via extraction well W-830-2216, which has resumed consistent operation with the recent completion of engineering upgrades at the CGSA GWTS. The contamination in this area likely arises from a combination of sources located in both the HEPA and Building 832 Canyon OUs. Decreasing VOC concentration trends in this extraction well and nearby monitor well W-830-13 suggest that remediation has been effective in removing mass in this area.

$Tnsc_{1ab}$ HSU

Active remediation of the $Tnsc_{1ab}$ HSU began in 2000 and the extraction wellfield currently consists of ten groundwater extraction wells and five dual extraction wells. Water levels continue to decline in both the 830-SRC and 832-SRC areas, limiting continuous extraction from the $Tnsc_{1b}$ and $Tnsc_{1a}$ stratigraphic intervals that comprise the $Tnsc_{1ab}$ HSU. Upgrades have been made to existing 832-SRC extraction wells to increase operational time and increase mass removal. Also, connection of well W-832-2020, a groundwater extraction well, and well W-832-3019, a dual extraction well, is complete. Full operation of 832-SRC resumed briefly for portions of October and November 2022 and will resume full operation after freeze protection ends in 2022.

Upper $Tnbs_1$ HSU

Extraction wells in the Upper $Tnbs_1$ HSU target areas with the highest TVOC concentrations. Since remediation began in this HSU, the overall extent of VOCs has decreased significantly and concentrations in monitor well W-830-1832 have been below reporting limits since March 2010. Groundwater in Upper $Tnbs_1$ guard wells W-830-15 and W-832-2112, located downgradient of well W-830-1832 and upgradient of water-supply Well 20, continues to exhibit concentrations below reporting limits for all COCs except nitrate concentrations, which were significantly below the 45 mg/L MCL cleanup standard.

Mass Removal

In the Building 832-SRC area, COC concentration trends in extraction wells have remained stable for several years, as declining water levels and low yields limit groundwater extraction. During 2021, after intermittent minimal operation of the 832-SRC SVTS through the first and second semesters, both the 832-SRC GWTS and SVTS began full operation on October 19 and operated until being secured for freeze protection on November 22. In total during 2021, 11,000 gal of groundwater and 187,000 cubic ft of soil vapor were extracted and treated. A total of 8.1 g of VOCs, 0.21 g of perchlorate, and 3.5 kg of nitrate were removed from groundwater and a total of 637 g of VOC mass was removed from soil vapor (Table Summ-1). When the facility is again brought online full time, the addition of dual extraction well W-832-3019, groundwater extraction well W-832-3020, other engineering upgrades, and the facility rebuild will result in increased mass removal rates in this area for both soil vapor and groundwater. The data acquisition capabilities added as part of these completed upgrades will also provide data needed to better optimize mass removal from existing wells in this area.

The 830-SRC GWTS and SVTS were secured from January 1 to April 6 for freeze protection and operated except for the instances described in Table 2.5. In total, during 2021, 1.245 million gal of groundwater and 1.538 million cubic ft of soil vapor were treated. This represents a 20% increase for groundwater and a very significant increase for soil vapor from 2020 (1.025 million gal of groundwater and 435,000 cubic ft of soil vapor). During 2021, a total of 427 g of VOCs, 1.3 g of perchlorate, and 49 kg of nitrate were removed (Table Summ-1), which is roughly equal to the total masses removed in 2020 due to decreased concentrations. Operational maintenance and engineering upgrades are planned for the misting towers to increase operational runtime and the efficacy of the misting discharge process. As noted in Section 2.7.1.4, DOE/LLNL continues to evaluate long-term alternatives for the final disposition of treated effluent. These options include injection into wells or continuation of misting. Until a final decision is made on the disposition of treated effluent, groundwater will be discharged at the misting towers, as described above. Any proposed changes to the methods for discharge of treated effluent will be presented to the regulatory agencies for concurrence.

The 830-DISS GWTS was secured from January 1 to June 16 for freeze protection and also periodically through 2021 to accommodate shutdown and repairs of the CGSA GWTS, as noted in Table 2.5. During 2021, the facility operated with only one extraction well (W-830-2216) as the other wells did not contain sufficient head to flow freely at the surface. During 2021, approximately 334,000 gal of groundwater was extracted and treated. A total of 3.6 g of VOCs, 4.4 g of perchlorate, and 83 kg of nitrate were removed from extracted groundwater (Table Summ-1).

As remediation proceeds from the 832-SRC, 830-SRC, and 830-DISS extraction wells, contaminant concentrations in all Building 832 Canyon HSUs are expected to continue to decline. The anticipated long-term decline in water levels will have an impact on long-term performance of extraction wells. VOC concentration trends in the Upper $Tnbs_1$ HSU continue to be monitored closely, because changes to the pumping schedules of water-supply Well 20 and backup water-supply Well 18 have the potential to hydraulically influence the vertical distribution of contaminants.

2.7.3.4. Building 832 Canyon OU Remedy Performance Issues

No other new issues were identified during this reporting period that could impact the long-term performance of the cleanup remedy for the Building 832 Canyon OU. The remedy continues to make progress toward cleanup, and to be protective of human health and the environment.

2.8. Site 300 Site-Wide (OU 8)

2.8.1. Building 801 and Pit 8 Landfill

The Building 801 Firing Table was used for explosives testing until it was discontinued in 1998, and the firing table gravel and some underlying soil were removed. Waste fluid discharges to the Building 801D dry well from the late 1950s to 1984 resulted in VOC contamination of soil and groundwater. Debris from the firing table was buried in the nearby Pit 8 Landfill until 1974. A map of the Building 801 and Pit 8 Landfill area showing the locations of the buildings, firing table, landfill, and monitor wells is presented on Figure 2.8-1.

2.8.1.1. Building 801 and Pit 8 Landfill Groundwater Monitoring

Wells K8-01, -02B, -03B, -04, and -05, and wells W-PIT8-3201, -3202, and -3203 monitor groundwater for contaminants that may have been released from the Building 801 Firing Table and facilities, or the Building 801D dry well. Wells K8-02B, -04, and -05, and wells W-PIT8-3201, -3202, and -3203 are also used to detect potential chemical releases from the Pit 8 Landfill. Detection monitoring of this landfill, which is discussed in Section 3.4, is conducted to determine if releases have occurred.

The sampling and analysis plan for groundwater and surface water monitoring for the full year is presented in Appendix C. This table also explains deviations from the sampling plan and indicates any additions made to the CMP.

Wells in this area are scheduled for sampling and analysis primarily during the second quarter of the calendar year. During the first semester of 2021, groundwater monitoring was conducted in accordance with the CMP monitoring requirements with the following exceptions: a total of 12 required analyses for three different wells were not performed for: well K8-02B due to a failed pump resulting in two missed analyses, well K8-03B with a missed nitrate analysis due to analytical laboratory equipment issues, and well K8-05, which was dry, resulting in nine analyses that could not be performed.

During the second semester of 2021, all 2021 CMP monitoring requirements were met.

2.8.1.2. Building 801 and Pit 8 Landfill Contaminant Concentrations and Distribution

At Building 801, the VOCs CFORM, 1,2-DCA, and TCE are the primary COCs detected in groundwater; perchlorate and nitrate are the secondary COCs. There are no COCs in groundwater attributable to the Pit 8 Landfill. The results of the detection monitoring of the Pit 8 Landfill are discussed in Section 3.3.

In the Building 801/Pit 8 Landfill area, eight monitor wells are screened in the $Tnbs_1$/$Tnbs_0$ HSU. Well K8-05, which is scheduled to be sampled during odd years, has been dry since it was installed in 1988.

Groundwater elevations and COC concentrations for 2021 are shown on Figure 2.8-1.

General trends of primary and secondary COC concentrations in the $Tnbs_1$/$Tnbs_0$ HSU:

- The historical maximum TVOC concentration is 10 µg/L, detected in 1990 in well K8-01.
- TVOC concentrations decreased to a 2021 maximum of 3.9 µg/L, detected in May in well K8-01.
- The historical maximum TCE concentration is 6.0 µg/L, detected in 1992 in well K8-01.
- TCE has decreased to a current 2021 maximum of 2.8 µg/L, detected in May in well K8-01.
- The historical maximum 1,2-DCA concentration is 5.0 µg/L, detected in 1990 in well K8-01.
- 1,2-DCA has decreased to a 2021 maximum of 1.2 µg/L, detected in May in well K8-01.
- The historical maximum CFORM concentration is 2.4 µg/L, detected in 1992 in well K8-01.
- Including 2021, CFORM has remained below the 0.5 µg/L reporting limit in all area wells since 2008.
- Including 2021, the historical maximum perchlorate concentration is 5.0 µg/L, detected in 2003 in well K8-04.
- Perchlorate was detected at 7.1 µg/L in a December sample from well K8-04; however, a duplicate sample collected at the same time and analyzed by a different laboratory yielded 4 µg/L of perchlorate.
- The historical maximum nitrate concentration is 80 mg/L, detected in 2015 in well K8-04.
- Nitrate has decreased to a 2021 maximum of 73 mg/L, detected in May in well K8-04.

As was the case in 2020, the 2021 maximum TVOC concentration (3.9 µg/L) in the area was observed in well K8-01 (comprised of 2.8 µg/L of TCE and 1.1 µg/L of 1,2-DCA). These concentrations are well within the range observed since 1990.

Of the groundwater COCs, only 1,2-DCA was detected above its MCL cleanup standard and reporting limit (both 0.5 µg/L) during 2021 in two wells: K8-01 (1.2 µg/L and 1.1 µg/L, May routine and duplicate samples, respectively, and 1.1 µg/L and 0.71 µg/L, December duplicate and routine samples, respectively) and K8-04 (1.0 µg/L and 0.99 µg/L, May duplicate and routine samples, respectively). Additionally, 1,2-DCA was not detected above the 0.5 µg/L reporting limit in samples from the remaining wells, including W-PIT8-3203, which yielded 0.72 µg/L of 1,2-DCA in August 2016. During 2021, TCE was not detected above its 5 µg/L MCL cleanup standard and CFORM was not detected above its 0.5 µg/L reporting limit in any Building 801/Pit 8 monitor well samples. Overall, TVOC concentrations detected in groundwater samples collected from wells downgradient of Building 801 have decreased since 1990.

The spatial extent of the VOCs TCE and 1,2-DCA has generally remained unchanged. The presence of VOC maxima in well K8-01 (located immediately downgradient of Building 801 and upgradient of the Pit 8 Landfill) and lower concentrations observed intermittently in well K8-04 (located immediately downgradient of the Pit 8 Landfill) defines a continuation of the VOC plume originating at the Building 801D dry well. Thus, this plume does not originate from the Pit 8 Landfill.

In 2021, perchlorate was detected in two area wells. A December routine sample from well K8-04 yielded 7.1 µg/L, represented the historical maximum, and was the first time perchlorate concentrations ever exceeded the 6 µg/L MCL cleanup standard in area wells. However, a duplicate sample from the same well was analyzed by a different laboratory and yielded 4 µg/L of perchlorate. Therefore, the 7.1 µg/L detection may be anomalous. In 2021, perchlorate was also detected in one other well, K8-01, at 2.6 µg/L and 2.0 µg/L, in December duplicate and routine samples, respectively. However, it is noteworthy that during 2021, the laboratory reporting limit for perchlorate was lowered from 4 µg/L to 2 µg/L. In 2019 and 2020, perchlorate was not detected above the previous 4 µg/L reporting limit in any Building 801/Pit 8 Landfill area wells. During 2018, perchlorate was detected slightly above its 4 µg/L reporting limit in two wells: 4.7 µg/L in the July sample from well W-PIT8-3203 and 4.1 µg/L in the May duplicate sample from well K8-04 (it did not exceed the 4 µg/L reporting limit in the routine sample). Prior to December 2021, perchlorate concentrations had never exceeded the 6 µg/L MCL cleanup standard in Building 801/Pit 8 Landfill area wells. Perchlorate concentrations will be closely monitored in well K8-04 and other wells for future trends.

The 2021 maximum nitrate concentration was 73 mg/L and 71 mg/L in well K8-04 (May routine and duplicate samples, respectively). The same well yielded the maximum nitrate concentrations in 2020 at 71 mg/L and 2019 at 73 mg/L, which are similar to recent results. The historical maximum nitrate concentration is 80 mg/L in well K8-04 in 2015. Since 2004, nitrate concentrations in this well have ranged from 51 mg/L to 80 mg/L. Nitrate was also detected in two other wells, slightly above the 45 mg/L MCL cleanup standard, at 59 mg/L and 56 mg/L (well W-PIT8-3203, December and May, respectively), and 47 mg/L (duplicate sample from well K8-01, May; the routine sample yielded 44 mg/L). The nitrate concentrations in wells K8-01 and W-PIT8-3203 are consistent with previous results, which have, since 2016, ranged from 36 mg/L to 49 mg/L in well K8-01, and 46 mg/L to 61 mg/L in well W-PIT8-3203. Nitrate concentrations in other Pit 8 area wells did not exceed the 45 mg/L MCL cleanup standard during 2021. Nitrate concentrations detected in Building 801/Pit 8 Landfill area groundwater during 2021 are generally similar to previous years.

Nitrate, 1,2-DCA, and possibly perchlorate, are the only COCs with concentrations above their MCL cleanup standards at the Building 801/Pit 8 Landfill area.

2.8.2. Building 833

TCE was used as a heat-exchange fluid at Building 833 from 1959 to 1982, and was released through spills and rinse water disposal, resulting in TCE contamination of soil and shallow perched groundwater. A map showing the locations of the building and monitor wells is presented on Figure 2.8-2.

2.8.2.1. Building 833 Groundwater Monitoring

The sampling and analysis plan for groundwater and surface water monitoring for the full year is presented in Appendix C. This table also explains deviations from the sampling plan and indicates any additions made to the CMP.

During 2021 groundwater monitoring was conducted in accordance with the CMP monitoring requirements for three wells in this area. Eight scheduled analyses from eight wells were not conducted, because the wells were dry. The dry wells have generally contained insufficient or no groundwater for sampling since 1993.

2.8.2.2. Building 833 Contaminant Concentrations and Distribution

At Building 833, the VOCs TCE and *cis*-1,2-DCE are the primary COCs in shallow, perched groundwater; there are no secondary COCs. The Tpsg HSU is an ephemeral, perched water-bearing zone equivalent to the contaminated HSU in the Building 834 OU. During heavy rainfall events, this HSU may become saturated. Quarterly monitoring of these wells from 1993 to present has shown variable levels of saturation, including many wells that are now dry (W-833-03, -12, -18, -22, -28, -33, -34, and -43). When saturated, monitoring conducted since 1988 has shown a significant decline in VOC concentrations in Tpsg HSU groundwater compared to the highest concentrations, which were observed in the early 1990s.

In the Building 833 area, eight monitor wells are screened in the Tpsg HSU, one well (W-841-01) is screened in the Upper $Tnbs_1$ HSU and two wells (W-833-30 and W-840-01) are screened in the Lower $Tnbs_1$ HSU.

During 2021, only three wells had sufficient water available for sampling: Lower $Tnbs_1$ HSU wells W-833-30 and W-840-01, and Upper $Tnbs_1$ HSU well W-841-01. All three wells yielded concentrations below individual reporting limits for TVOCs (0.5 µg/L).

Groundwater elevations and contaminant concentrations for 2021 are shown on Figure 2.8-2.

2.8.3. Building 845 Firing Table and Pit 9 Landfill

The Building 845 Firing Table was used from 1958 until 1963 to conduct explosives experiments. Leaching from firing table debris resulted in minor contamination of subsurface soil with depleted uranium and HMX. A map showing the locations of the building, landfill, and monitor wells is presented on Figure 2.8-3.

2.8.3.1. Building 845 and Pit 9 Landfill Groundwater Monitoring

No groundwater COCs have been identified for the Building 845/Pit 9 Landfill area. Seven wells (K9-01, -02, -03, and -04; W-PIT9-3204, -3205, and -3206) monitor area groundwater to:

- Detect any potential future releases from the Pit 9 Landfill; and
- Detect any potential impacts to groundwater from HMX and uranium (subsurface soil COCs).

These monitor wells are screened in the Lower Neroly Formation $Tnbs_1$/$Tnbs_0$ HSU. Detection monitoring of the Pit 9 Landfill is discussed in Section 3.5.

The sampling and analysis plan for groundwater and surface water monitoring for the full year is presented in Appendix C. This table also explains deviations from the sampling plan and indicates any additions made to the CMP.

During 2021, groundwater monitoring was conducted in accordance with the CMP monitoring requirements for five of the seven wells in this subarea. No samples could be collected from wells W-PIT9-3205 and -3206 for 16 scheduled analyses because the wells were inaccessible. The remaining wells (K9-01, K9-02, K9-03, K9-04, and W-PIT9-3204) were sampled during 2021 in accordance with the CMP monitoring requirements.

2.8.3.2. Building 845 and Pit 9 Landfill Contaminant Concentrations and Distribution

In the Building 845 and Pit 9 Landfill area, seven landfill detection monitor wells are screened in the $Tnbs_1$/$Tnbs_0$ HSU. All the scheduled analyses for the detection monitoring constituents (VOCs,

nitrate, tritium, perchlorate, HE compounds, uranium isotopes, Title 22 metals, lithium, and fluoride) were performed during the first semester of 2021 for wells K9-01, -02, -03, and -04, and W-PIT9-3204.

The concentrations and activity concentrations of the detection monitoring constituents (VOCs, nitrate, tritium, perchlorate, HE compounds, uranium isotopes, Title 22 metals, lithium, and fluoride) in the 2021 samples were either below reporting limits or within the range of background.

Because uranium and HMX were identified as COCs in subsurface soil at Building 845/Pit 9 Landfill, groundwater in this area is monitored for these constituents.

During 2021, HMX concentrations in groundwater samples remained below the 1 µg/L reporting limit. Historically, HMX has not been detected above its reporting limit since 1989, when the first monitor wells were installed in the area.

During 2021, total uranium activity concentrations in groundwater samples from all five wells sampled remained very low (<0.37 pCi/L), well below both the 20 pCi/L MCL cleanup standard for total uranium and background levels. The $^{235}U/^{238}U$ atom ratio, as determined by mass spectrometry, where quantifiable, indicated the presence of only natural uranium in the five wells sampled.

The results of the Pit 9 Landfill detection monitoring are discussed in Section 3.5.

Groundwater elevations and contaminant concentrations/activities for 2021 are shown on Figure 2.8-3.

2.8.4. Building 851 Firing Table

The Building 851 Firing Table has been used since 1962 to conduct explosives experiments. Some of the experiments conducted prior to 2008 contained depleted uranium. A map depicting the locations of the firing table and monitor wells is presented on Figure 2.8-4.

2.8.4.1. Building 851 Groundwater Monitoring

The sampling and analysis plan for groundwater and surface water monitoring for the full year is presented in Appendix C. This table also explains deviations from the sampling plan and indicates any additions made to the CMP.

During 2021, groundwater monitoring was conducted in accordance with the CMP monitoring requirements for all six wells in this subarea.

2.8.4.2. Building 851 Contaminant Concentrations and Distribution

In the Building 851 Firing Table area, six monitor wells (W-851-05, -06, -07, and -08; and W-851-3207 and -3208) are screened in the Tmss HSU. Uranium is the primary and only COC detected in groundwater; there are no secondary COCs. Uranium is a groundwater COC, because historical mass spectrometric analysis previously confirmed the presence of some depleted uranium in groundwater samples.

Uranium activity concentrations in Tmss HSU groundwater in the Building 851 Firing Table area have always been well below the 20 pCi/L MCL cleanup standard and within the range of background. Although background uranium activity concentrations at Site 300 may vary based on groundwater age, major-ion chemistry, and aquifer lithology, single-digit uranium activity concentrations are clearly within the range of Site 300 background. However, groundwater continues to be monitored to detect any impacts from depleted uranium in surface and subsurface soil and rock.

Groundwater elevations and uranium activity concentrations for 2021 are shown on Figure 2.8-4.

General trends of primary COC activity concentrations in the Tmss HSU:

- The historical maximum uranium activity concentration is 7.9 pCi/L, detected in 2016 in well W-851-3207.
- Uranium activity concentrations have decreased over time, remaining relatively stable since 1998. The current 2021 maximum of 1.9 pCi/L in June, was detected in well W-851-3207, within a range of uranium activity concentrations observed in this well. The historical maximum in this well is 2.1 pCi/L, detected in 1993.

The aforementioned 2021 maximum total uranium activity concentration of 1.9 pCi/L in well W-851-3207 was associated with a $^{235}U/^{238}U$ atom ratio, as measured by mass spectrometry, indicative of a natural source of uranium, as has been the case historically. The other wells with a total uranium activity concentration above the laboratory reporting limit during the reporting period were W-851-08 (0.9 pCi/L, May), W-851-3208 (0.27 pCi/L, June), and W-851-07 (0.1 pCi/L, (May). While the uranium detections in wells W-851-08 and W-851-3208 were accompanied by $^{235}U/^{238}U$ atom ratios, indicating a natural source for the uranium, the detection in well W-851-07 accompanied by a $^{235}U/^{238}U$ atom ratio of 0.00696, indicated a very slight depleted uranium content.

Historically, the $^{235}U/^{238}U$ atom ratio in this well has indicated a natural source for the uranium. In 2020, the maximum total uranium activity concentration detected in the Building 851 area was 3.0 pCi/L (June) in well W-851-3207; this is similar to the maxima detected in this area in the same well in May of the previous two years (3.6 pCi/L, 2019, and 3.9 pCi/L, 2018). The historical maximum uranium activity concentration in Tmss HSU groundwater is 7.9 pCi/L, detected in well W-851-3207 in October 2016. The $^{235}U/^{238}U$ atom ratio for this 2020 sample and historically from this well, as measured by mass spectrometry, indicates a natural source of uranium.

The inability to quantify $^{235}U/^{238}U$ atom ratios for some groundwater samples from the Building 851 area arises regularly, because of low ^{235}U concentrations that are often below mass spectrometry reporting limits. In this report, these $^{235}U/^{238}U$ atom ratios are quantified as "<" values due to the "<" value in the numerator. For strict correctness, these ratios should be reported as non-quantifiable (NQ) as shown on Figure 2.8-4. DOE/LLNL will correct the reporting of these $^{235}U/^{238}U$ atom ratios in the near future. Overall, uranium activity concentrations in groundwater during the reporting period are similar to previous years and remain well below the 20 pCi/L MCL cleanup standard.

In May and December of 2021 (as well as in June and November 2020, October 2018, and November 2019), discretionary groundwater samples were collected from the six monitor wells in the study area (except for well W-851-3208, which was inaccessible for the November 2019 event) and analyzed for VOCs, nitrate, perchlorate, metals, and HE compounds. No VOCs were detected in excess of the 0.5 µg/L individual compound reporting limit in any 2018, 2019, 2020, or 2021 samples. During 2021, except for an October 1.1 mg/L detection of nitrate in well W-851-08, nitrate and perchlorate were not detected in any sample in excess of their reporting limits of 1 mg/L and 4 µg/L, respectively. Of the metals, only barium was detected slightly in excess of its laboratory reporting limit (well W-851-08, May and October), well within natural background ranges. HE compounds were not detected in any samples from the six sampled wells in excess of individual compound reporting limits. These analytical results for 2018, 2019, 2020, and 2021, indicate no impact to groundwater from any of these constituents.

3. Detection Monitoring, Inspection, and Maintenance Program for the Pit 1, 2, 3, 4, 5, 6, 7, 8, and 9 Landfills and Inspection and Maintenance Program for the Drainage Diversion System and Building 850 CAMU

The Detection Monitoring Program is designed to detect any future releases of contaminants from the Pits 1, 2, 3, 4, 5, 6, 7, 8, and 9 Landfills. This section presents the results of groundwater detection monitoring of these landfills, and any landfill inspections or maintenance conducted during the reporting period.

3.1. Pit 1 Landfill

From 1961 to 1988, the Pit 1 Landfill received debris from the firing tables in the East Firing Area. In 1989, the Pit 1 Landfill was closed. Under RCRA, during 1991-1992, Pit 1 was covered with an engineered low permeability cap.

The current groundwater monitoring network at Pit 1 consists of 12 wells. These wells include eight detection monitor wells and four evaluation monitor wells. The detection monitor wells used to sample the groundwater in the vicinity of Pit 1 include: wells K1-01C and K1-07, located hydrologically upgradient from Pit 1; downgradient wells K1-02B, K1-04, K1-05, and W-PIT1-2326; and cross-gradient wells K1-08 and K1-09. The primary purpose of the detection monitor wells is to detect any new releases of COCs to groundwater. The evaluation monitor wells are all downgradient of the Pit 1 detection wells and include K1-06, W-PIT1-2620, W-PIT1-2209, and W-865-2005. These evaluation monitor wells were added to the Pit 1 monitoring and reporting requirements to track existing plumes of perchlorate and tritium from upgradient sources. LLNL collects and analyzes one sample quarterly from each evaluation monitor well.

Sampling and Analysis Plan Modifications

During the second semester of 2021, samples for 16 analyses were not collected from two wells due to insufficient water and issues with sampling equipment.

Detection and Evaluation Monitoring Results

Monitoring data indicate that there were no new releases of contaminants from Pit 1 during 2021. Constituent concentrations and activity concentrations generally remained stable between 2020 and 2021. Depth to groundwater beneath Pit 1 was an average of about 120 ft bgs during 2021.

During the second semester of 2021, ten of the 12 Pit 1 groundwater monitoring network wells were sampled for metals and the other detection monitoring constituents. Monitor wells K1-06 and K1-07 were not sampled due to the reasons specified above.

Metals

Nine Pit 1 groundwater monitoring network wells contained arsenic concentrations above the Title 22 (California) drinking water MCL of 0.010 mg/L. Wells K1-08 and K1-09 exhibited the maximum arsenic concentration of 0.016 mg/L (February and January, respectively). Arsenic concentrations in Pit 1 groundwater monitoring network wells have remained stable for the past five years, with concentrations ranging from 0.002 to 0.017 mg/L. These arsenic concentrations are typical of groundwater in other parts of Site 300 and appear to represent background conditions.

Nine Pit 1 groundwater monitoring network wells contained barium in excess of the reporting limit of 0.025 mg/L, but all concentrations were below the state MCL of 1 mg/L. Barium concentrations in the Pit 1 groundwater monitor wells remained stable between 2020 and 2021.

During 2021, beryllium was not detected in any Pit 1 well in excess of the 0.0005 mg/L reporting limit, as was the case for 2020. The state MCL for beryllium is 0.004 mg/L.

During 2021 cadmium was not detected in any Pit 1 well in excess of the reporting limit or 0.005 mg/L state MCL, as was the case for 2020.

During 2021, cobalt, copper, lead, and nickel were not detected in any of the Pit 1 wells in excess of their individual reporting limits of 0.025, 0.01, 0.002, and 0.005 mg/L, respectively; this was also the case in 2020.

During 2021, manganese was detected above the reporting limit of 0.03 mg/L in upgradient well K1-07 at a concentration of 0.15 mg/L. This concentration is within historical ranges.

During 2021, mercury was detected above the reporting limit of 0.0002 mg/L in downgradient well K1-05 at a concentration of 0.00021 mg/L. This concentration is within historical ranges.

During 2021, selenium was detected in five Pit 1 wells in excess of the 0.002 mg/L reporting limit, but below the state MCL of 0.05 mg/L. Selenium concentrations in the Pit 1 groundwater monitoring network remained stable between 2020 and 2021.

During 2021, zinc was detected in seven of the Pit 1 detection monitoring network wells in excess of the 0.02 mg/L reporting limit with a maximum of 0.026 (August) in well W-PIT1-2326. Zinc was detected in four wells in 2020 (K7-01, K1-05, K1-01C, and K1-02B), with a maximum of 0.034 mg/L in well K1-01C.

During 2021, vanadium was detected in excess of the 0.025 mg/L reporting limit in nine wells in the Pit 1 groundwater monitoring network. The maximum vanadium concentration was detected in well K1-01C (0.073 mg/L, December). Vanadium concentrations in the Pit 1 groundwater monitoring network remained stable between 2020 and 2021. There is no federal or state MCL for vanadium.

Nitrate and Perchlorate

During 2021, W-PIT1-2209, located downgradient of Pit 1, contained nitrate concentrations above the 45 mg/L MCL cleanup standard (68 mg/L, October), a minor increase from the 2020 maximum of 64 mg/L in W-PIT1-2620. In 2020, two wells, W-PIT1-2620 and W-PIT1-2209, contained nitrate concentrations exceeding the 45 mg/L MCL cleanup standard (64 mg/L and 48 mg/L, respectively). Well W-PIT1-2620 was not sampled for nitrate in 2021 due to inoperable sampling equipment.

During 2021, perchlorate was not detected at a concentration above the 6 µg/L MCL cleanup standard in any Pit 1 monitor wells. In 2020, one well, W-PIT1-2620, contained perchlorate at a concentration above the 6 µg/L MCL cleanup standard (7.2 µg/L). W-PIT1-2620 exhibited a perchlorate concentration of 5.9 µg/L (November) in 2021.

For the past five years, nitrate and perchlorate concentrations in the Pit 1 area have generally been temporally and spatially stable.

Tritium

Tritium activity concentrations have remained stable for the past five years and are well below the 20,000 pCi/L MCL cleanup standard. The maximum 2021 tritium activity concentration at Pit 1 was 2,420 pCi/L (August) at downgradient well K1-02B. This is a minor decrease from the 2020 maximum

tritium activity concentration, which was 2,690 pCi/L from the same well. Tritium observed in groundwater samples from the Pit 1 area in excess of background is related to upgradient sources in the Building 850 portion of OU 5.

Uranium

Total uranium activity concentrations at Pit 1 have remained stable for the past five years and are well below the 20 pCi/L MCL. The 2021 maximum total uranium activity concentration at Pit 1 was 5.7 pCi/L (November) at well W-PIT1-2620, a minor increase from the 2020 maximum total uranium activity concentration of 5.5 pCi/L in the same well. Previous studies indicate that the uranium $^{235}U/^{238}U$ atom ratios observed in the Pit 1 monitor wells are natural and within the range of background (Chan, 2020).

Other Constituents

During 2021, HMX, RDX, radium-226, thorium-228, and thorium-232 were not detected in groundwater in any of the Pit 1 monitoring network wells in excess of individual reporting limits.

Landfill Inspection Results

The Pit 1 Landfill cap annual engineering inspection was performed on March 29, 2021. Inspection results are summarized in the Pit 1 Cap Annual Engineering Inspection Report (Abri Environmental Engineering, 2021a). The report states that the cap on Pit 1 was in good condition, the vegetation cover was thick and covered the cap, there was no visible erosion, the drainage system was in good condition and appeared to be functioning as intended, and the groundwater monitoring system was in good condition.

The routine LLNL inspection of the Pit 1 Landfill cap was performed on April 7, 2021. Results from the inspection indicate that the landfill cap was in good overall condition.

Annual Subsidence Monitoring Results

Annual subsidence monitoring was conducted during the second semester of 2021. No evidence of subsidence was detected

Maintenance

Maintenance was performed on the Pit 1 cap on October 7, 2021. Maintenance included removing vegetative debris and sediment from the drainage ditch and the dissipator, removing weeds from drainage ditch joints, resealing all drainage ditch points, and filling animal burrows.

3.2. Pit 2 Landfill

The Pit 2 Landfill was used from 1956 to 1960 to dispose of firing table debris from Buildings 801 and 802. Groundwater data indicate that a past discharge of potable water to support a red-legged frog habitat located upgradient of the landfill may have leached depleted uranium from the buried waste. The frogs were relocated, and the water discharge was discontinued, thus removing the leaching mechanism. No COCs were identified in surface or subsurface soil at the Pit 2 Landfill. No risk to human or ecological receptors has been identified at the Pit 2 Landfill.

Sampling and Analysis Plan Modifications

Detection monitoring of wells located downgradient of the Pit 2 Landfill is conducted annually for VOCs, nitrate, tritium, perchlorate, HE compounds, uranium isotopes, Title 22 metals, lithium, and fluoride. The detection monitor wells include W-PIT2-1934, W-PIT2-1935, K2-01C, and NC2-08.

The sampling and analysis plan for the Pit 2 Landfill groundwater detection monitoring program is presented in Appendix C.

During 2021, two requested analyses from one Pit 2 monitor well were not performed due to insufficient water.

Contaminant Detection Monitoring Results

A map showing monitor wells and the Pit 2 Landfill is presented on Figure 2.5-1. Depth to groundwater within the $Tnbs_1/Tnbs_0$ HSU beneath the landfill currently ranges from 45 ft to over 70 ft.

Tritium

The 2021 maximum tritium activity concentration within the $Tnbs_1/Tnbs_0$ HSU in the area immediately south of the Pit 2 Landfill was 2,000 pCi/L in a May groundwater sample collected from detection monitor well K2-01C; this is a slight decrease from the 2020 maximum of 2,180 pCi/L in the same well. The historic maximum tritium activity concentration of 49,100 pCi/L was detected in groundwater samples collected from detection monitor well K2-01C in 1986. Overall, tritium activity concentrations in the Pit 2 Landfill detection monitor wells are stable to declining over the last few years.

Uranium

The 2021 maximum uranium activity concentration in the Pit 2 area was 5.7 pCi/L (November) in detection monitor well W-PIT2-2620; this is below the 20 pCi/L MCL cleanup standard and within the range of natural background (Ferry et al., 1999). Uranium activity concentrations in the Pit 2 area continue to decrease from the 27.4 pCi/L maximum measured in a 1994 groundwater sample collected from well K2-01C. As stated above, prior to 2005, to maintain a wetland habitat for red-legged frogs (a federally listed endangered species), potable water was discharged within the drainage channel that extends south and along the northern and eastern margin of the Pit 2 Landfill. While this discharge occurred, increased uranium activity concentrations and declining $^{235}U/^{238}U$ atom ratios were observed in Pit 2 area wells. The $^{235}U/^{238}U$ atom ratios in groundwater from wells K2-01C, W-PIT2-1934, and W-PIT2-1935 indicated the presence of depleted uranium. Release of depleted uranium from Pit 2 appears to have occurred, as a result of this discharge. This discharge was discontinued in 2005 and since then, total uranium activities in groundwater collected from the Pit 2 detection monitor wells have decreased and $^{235}U/^{238}U$ atom ratios continue an increasing trend toward a natural $^{235}U/^{238}U$ atom ratio (approximately 0.0072).

During 2021, $^{235}U/^{238}U$ atom ratios in groundwater collected from wells NC2-08, W-PIT2-1935, K2-01C and W-PIT2-1934 (0.00712, 0.00717, 0.00717 and 0.00667 (May), respectively) indicated the minor presence of depleted uranium, with similar ratios to those observed in 2020.

Nitrate and Perchlorate

During 2021, perchlorate was detected in two Pit 2 detection monitor wells, K2-01C and W-PIT2-1935, at 4.6 µg/L (May) and 2.5 µg/L (November), respectively. During 2021, nitrate

concentrations exceeded the 45 mg/L MCL cleanup standard in one well, W-PIT2-1934 (49 mg/L, May).

Concentrations of the other detection monitoring constituents (VOCs, HE compounds, metals, lithium, and fluoride) in samples collected during 2021 were either below reporting limits or within the range of background (Ferry et al., 1999). There was no evidence of new contaminant releases from the Pit 2 Landfill indicated by the 2021 groundwater detection monitoring data.

Landfill Inspection Results

The Pit 2 Landfill cover was inspected on January 25, April 7, July 13, and October 13, 2021. No maintenance issues were identified.

Annual Subsidence Monitoring Results

Annual subsidence monitoring was conducted during the second semester of 2021. No evidence of subsidence was detected

Maintenance

No maintenance was needed at Pit 2 during 2021.

3.3. Pit 6 Landfill

The Pit 6 Landfill was used from 1964 to 1973 to bury waste in nine unlined debris trenches and animal pits, including shop and laboratory equipment, and biomedical waste. The Pit 6 Landfill was capped and closed in 1997 to prevent further leaching of contaminants that likely resulted from percolation of rainwater through the buried waste. Detection monitoring of the Pit 6 Landfill is conducted to identify any future releases to groundwater in accordance with the requirements of the Pit 6 Post-Closure Plan (Campbell and Taffet, 2007).

Sampling and Analysis Plan Modifications

Detection monitoring of wells located downgradient of the Pit 6 Landfill (EP6-06, EP6-08, EP6-09, K6-01S, K6-19, and K6-36) is conducted semi-annually for VOCs and tritium, and annually for aromatic VOCs (benzene, toluene, ethylbenzene, and xylenes), beryllium, mercury, total uranium, gross alpha/beta radioactivity, perchlorate, and nitrate. When detection monitor well K6-01S is dry, deeper well K6-01 serves as an alternate detection monitor well and is sampled for the same constituents. Well K6-01S had available groundwater for sampling during the reporting period, so well K6-01 was not needed as an alternate detection monitor well.

Since 2009, and until 2017, well EP6-08 was continuously dry. Well K6-36 has typically been dry since 2006. In 2013, wells EP6-07 (near well EP6-08) and K6-35 (near well K6-36) were designated as detection monitor wells and have since been sampled for the same constituents as the wells they replaced. Since 2017, and again this reporting period, well EP6-08 was sampled for post-closure constituents. Well K6-36 yielded groundwater and was successfully sampled for the detection monitoring constituents in January 2020 but was dry and not sampled in July 2020 and remained dry throughout the remainder of 2021.

The sampling and analysis plan for the Pit 6 Landfill groundwater detection monitoring program is presented in Appendix C.

During the second semester of 2021, groundwater monitoring was conducted in accordance with CMP requirements.

Contaminant Detection Monitoring Results

A map showing the locations of monitor wells at the Pit 6 Landfill is presented on Figure 2.3-1. The groundwater elevation contour map for the Qt-$Tnbs_1$ HSU is presented on Figure 2.3-2. The distribution of TVOCs and tritium in the Qt-$Tnbs_1$ HSU is presented on Figures 2.3-3 and 2.3-4, respectively. For 2021, groundwater analytical results are summarized in Attachment 1 and groundwater elevations measured during sampling are included in Appendix D. The 2021 groundwater detection monitoring data do not indicate evidence of a new contaminant release from Pit 6. The April, August, and October samples from well EP6-08 contained small concentrations of four VOCs, all below MCLs. At well EP6-09, TCE exceeded the MCL at 5.8 µg/L (February 2021) and concentrations declined to 4.4 µg/L (August 2021). These concentrations are likely a result of rising groundwater encountering residual VOCs in the vadose zone. During 2021, groundwater levels beneath the Pit 6 Landfill ranged from approximately 30 ft (in wells located within the Corral-Hollow-Carnegie Fault Zone) to 43 ft (in wells located north of the Corral-Hollow-Carnegie Fault Zone) below the buried waste.

Concentrations of COCs in samples collected during 2021 declined slightly from the previous year's data. In 2020, for the first time since 2006, well K6-36 yielded available groundwater and was sampled for the required detection monitoring constituents. Groundwater levels declined and well K6-36 could not be sampled, as scheduled, during the latter half of 2021. Sampling of well K6-35 was reinstated as an alternate detection monitor well. In 2021, well K6-01S also contained groundwater and was successfully sampled for the required detection monitoring constituents.

Tritium and VOCs were released to groundwater from the landfill prior to capping in 1998 and have been detected in samples from Pit 6 Landfill detection monitor wells. During 2021, tritium activity concentrations in all detection monitor wells were below reporting limits (100 pCi/L) and therefore, did not exceed statistical limits (SLs).

During January 2020, in well K6-36, 400 ±124 pCi/L of tritium was detected, the first time since 2006 that this well had available groundwater for sampling. This was the only sample from a Pit 6 detection monitor well that exceeded the 100 pCi/L reporting limit in 2021. An SL for tritium has not been established for well K6-36. This well has a historical tritium maximum of 2,150 pCi/L in 2000. Tritium activity concentrations at well K6-19 were below reporting limits (100 pCi/L) during 2021 (February and August) and 2020 (January and July). The SL for tritium in well K6-19 was revised from 100 pCi/L to 317 pCi/L, following a statistical analysis conducted in September 2013. Tritium activity concentrations in well K6-19 have declined since October 1999, when the historical maximum for Pit 6 monitor wells of 2,520 pCi/L was detected. Since then, tritium activity concentrations in this well have generally decreased to below the reporting limit and have always been well below the 20,000 pCi/L MCL cleanup standard (Campbell and Taffet, 2007; Blake et al., 2011). During 2021, tritium was detected at monitor well K6-22 (100 ±70.8 pCi/L, March 2021), at monitor well K6-24 (106 ±70.4 pCi/L, August 2021), and at monitor well K6-33 (114 ±69.0 pCi/L, March 2021; 137 ±73.9 pCi/L, August 2021). All other Pit 6 detection monitor wells were below the reporting limit of 100 pCi/L in 2021.

In 2017, after water was again present in EP6-08 for the first time in nine years, DOE/LLNL recommended that revised SLs be calculated after at least four quarters of recent baseline data for all detection monitoring constituents became available (Buscheck, et al. 2018). The sampling and analysis

frequency for this well was increased to quarterly, so that these data could be acquired for calculating SLs for this well. The analytical results for samples collected from well EP6-08 during 2021 are summarized below.

- Total uranium was detected at 8.5 pCi/L (April), 10.6 and 13.9 pCi/L (August routine and duplicate samples, respectively), and 12.4 and 10.7 pCi/L (October routine and duplicate samples, respectively). The 2021 results are comparable with the 2020 maximum of 10.1 pCi/L (November 2020). None of these activity concentrations exceeded the 20 pCi/L MCL. The historical maximum for total uranium is 23.92 pCi/L (January 2018) and the previous historical maximum was 9.65 pCi/L in 1997. A sample collected in April 2008 yielded a $^{235}U/^{238}U$ atom ratio that indicated the presence of only natural uranium. No other historical mass spectrometric atom ratio data are available for this well.
- Gross alpha radioactivity in EP6-08 was 6.01 ±2.29 pCi/L (April), 10.9 ±2.89 and 11.2 ±2.8 pCi/L (August routine and duplicate samples, respectively), and 20.5 ±4.81 pCi/L and 15.1 ±5.04 pCi/L (October routine and duplicate samples, respectively). The October routine and duplicate activity concentrations slightly exceeded the MCL cleanup standard of 15 pCi/L. The historical maximum for gross alpha radioactivity in well EP6-08 is 23.4 ±4.8 pCi/L in January 2018.
- Gross beta radioactivity in well EP6-08 was 8.7 ±1.9 pCi/L (April), 12.8 ±2.7 pCi/L and 14 ±2.7 pCi/L (August routine and duplicate samples, respectively), and 11.8 ±2.5 pCi/L and 12.8 ±2.6 pCi/L (October routine and duplicate samples, respectively). None of these nor any historical data exceeded the MCL cleanup standard of 50 pCi/L. The historical maximum for gross beta radioactivity in well EP6-08 is 27.3 ±4.4 pCi/L in 1996 and the second highest activity concentration is 18.9 ±4.1 pCi/L in 2006.
- TCE was also detected in well EP6-08 during the reporting period at 2.6 µg/L (April), 2.4 µg/L and 2.5 µg/L (August routine and duplicate samples, respectively), and 2.3 µg/L and 2.3 µg/L (October routine and duplicate samples, respectively). None of these detections exceeded the TCE MCL cleanup standard (5 µg/L). The TCE historical maximum for this well is 2.8 µg/L in 2019.
- During the reporting period, PCE was detected in well EP6-08 at 4.6 µg/L (April), 4.4 µg/L and 4.6 µg/L (August routine and duplicate samples, respectively), and 4.6 µg/L and 4.6 µg/L (October routine and duplicate samples, respectively). No detections in 2021 exceeded the MCL cleanup standard (5 µg/L). Results from 2021 show a slight concentration decline from the historical maximum (6.2 µg/L, January 2019) and the 2020 maximum (5.3 µg/L, November 2020). Groundwater samples collected since July 2017 have yielded the highest concentrations of PCE (2.8 µg/L to 6.2. µg/L) at well EP6-08. The previous maximum concentration was 1.7 µg/L in 2007.
- Well EP6-08 CFORM results during the reporting period of 0.85 µg/L (April), 0.78 µg/L and 0.85 µg/L (August routine and duplicate samples, respectively), and 1.4 µg/L and 1.4 µg/L (October routine and duplicate samples, respectively) were well below the MCL cleanup standard (80 µg/L).
- As stated above, tritium activity concentrations in two samples from well EP6-08 (August routine and duplicate samples) did not exceed reporting limits.

The uranium activity concentrations, gross alpha and beta radioactivities, and VOC concentrations detected at EP6-08 from 2017 to 2021 samples suggest mobilization of residual contamination in the vadose zone beneath Pit 6 adjacent to well EP6-08, as water levels rose approximately 8.5 ft from 2017 to 2020 as compared to the April 2008 sampling event. Water levels in this well are still over 42 ft below the bottom of the buried waste in the landfill and do not suggest a new release from the landfill.

A 2021 summary of COCs in other Pit 6 Landfill detection monitor wells is provided below.

Total uranium activity concentrations during 2021 in well K6-19 were 3.5 pCi/L (February), 4.7 pCi/L (April), 3.8 pCi/L (August), and 3.4 pCi/L (October), all of which are similar to 2020 results, indicating a continued decline from the 2018 maximum of 9.89 pCi/L (January). The historical maximum total uranium activity concentration in this well is 10.28 pCi/L in January 2017. The historical maximum detection corresponded with a 2.5 ft rise in water levels from October 2016 to January 2017. Historical $^{235}U/^{238}U$ atom ratios indicate the presence of only natural uranium, most recently in a sample collected in October 2018. The 2021 maximum total uranium activity of 4.75 pCi/L is well below the MCL cleanup standard of 20 pCi/L. Total uranium activities will continue to be closely monitored.

During the reporting period, gross alpha radioactivity did not exceed the MCL cleanup standard of 15 pCi/L or their respective SLs in any detection monitor wells, with the exception of well EP6-08 (20.5 ±4.8 pCi/L and 15.1±5.0 pCi/L in routine and duplicate samples respectively, October 2021). A gross alpha radioactivity SL has not been established for well EP6-08. The October detection of 20.5 ±4.81 pCi/L in well EP6-08 was the highest gross alpha radioactivity concentration in a Pit 6 detection monitor well during the reporting period. The historical maximum for gross alpha radioactivity at well EP6-08 is 35.2 pCi/L (May 1996). Minor detections of gross alpha radioactivity have occurred at well EP6-08 since water levels rose in 2017. Gross alpha activity concentrations show an overall decreasing trend since January 2018 (23.4 pCi/L). Well EP6-09 had exceedances of its SL of 4.9 pCi/L with 6.7 ±2.6 pCi/L (April 2021) and 7.9 ±2.9 pCi/L (October 2021). The 2021 gross alpha radioactivity results from well EP6-09 demonstrate a continued concentration decline from the historical maximum of 14.9 pCi/L (January 2019) following a rise in water levels in 2017.

During the reporting period, gross beta radioactivity did not exceed applicable SLs nor the MCL cleanup standard of 50 pCi/L in any Pit 6 Landfill detection monitor wells. The highest gross alpha radioactivity concentration in a Pit 6 detection monitor well during the reporting period was detected at well EP6-08 (12.8 ±2.7 pCi/L and 14 ±2.7 pCi/L in August 2021 routine and duplicate samples, respectively). The historical maximum gross beta radioactivity for this well is 27.3 pCi/L in 1996. The 2021 gross beta results from well EP6-08 indicate a continued decline in activity concentrations after activity concentrations increased in 2018 following a rise in water levels during 2017.

During 2021, VOCs were not detected in Pit 6 Landfill detection monitor wells above their SLs nor applicable MCL cleanup standards, except for a single detection of TCE exceeding the MCL cleanup standard at well EP6-09 (5.8 µg/L, February 2021). For all Pit 6 Landfill detection monitor wells, the highest concentrations of VOCs were TCE at 5.8 µg/L (well EP6-09, February 2021), PCE at 4.6 µg/L (well EP6-08, April, August, and October 2021), and *cis*-1,2-DCE at 2.2 µg/L (well K6-01S, August 2021), and chloroform at 1.4 µg/L (well EP6-08, October 2021). All other VOC concentrations were very low or below laboratory reporting limits. Further discussion of VOC concentrations at Pit 6 is presented in Section 0.

There was no evidence of new contaminant releases from the Pit 6 Landfill indicated by the 2021 groundwater detection monitoring data.

Landfill Inspection Results

LLNL inspected the Pit 6 Landfill on April 14, 2021. No maintenance issues were identified.

Abri Engineering conducted the Pit 6 Landfill Annual Engineering Inspection in April 2021 (Abri Environmental Engineering, 2021b). No maintenance issues were identified.

Annual Subsidence Monitoring Results

Annual subsidence monitoring was conducted by LLNL during the second semester of 2021. No evidence of subsidence was detected.

Maintenance

Maintenance was performed on the Pit 6 cap on October 7, 2021. Maintenance included removing vegetative debris from the drainage ditch and re-sealing drainage ditch joints.

3.4. Pit 8 Landfill

The Pit 8 Landfill received debris from the Building 801 Firing Table until 1974, when it was covered with about 2 ft of compacted soil.

Sampling and Analysis Plan Modifications

Detection monitoring of wells located downgradient of the Pit 8 Landfill (K8-02B, K8-04, K8-05, and W-PIT8-3203) is conducted annually for VOCs, nitrate, tritium, perchlorate, HE compounds, uranium isotopes, Title 22 metals, lithium, and fluoride. Data from monitor wells K8-01, W-PIT8-3202, W-PIT8-3201, and K8-03B, located upgradient of the Pit 8 Landfill and downgradient of the Building 801 area, are also used for comparative purposes.

The sampling and analysis plan for the Pit 8 Landfill groundwater detection monitoring program is presented in Appendix C.

Wells in this area are scheduled for sampling and analysis primarily during the second quarter of the calendar year. During the first semester of 2021, groundwater monitoring was conducted in accordance with the CMP monitoring requirements with the following exceptions: a total of 12 required analyses for three different wells were not performed for: well K8-02B due to a failed pump resulting in two missed analyses, well K8-03B with a missed nitrate analysis due to analytical laboratory equipment issues, and well K8-05, which was dry, resulting in nine analyses that could not be performed (this well has been dry since 1988). All second semester 2021 CMP monitoring requirements were met.

Contaminant Detection Monitoring Results

A map of the Building 801 Firing Table and Pit 8 Landfill area showing buildings, the former location of the Building 801 Firing Table, Pit 8, and monitor well locations is presented as Figure 2.8-1.

Historical and current data indicate that VOCs detected in groundwater in the Pit 8 Landfill area are the result of releases of VOCs from the former Building 801D dry well, which have migrated downgradient from Building 801 to beneath the landfill. During 2021, VOCs were detected in groundwater samples from wells in the vicinity of Pit 8. TCE was detected in wells K8-01, K8-02B, and K8-04; and 1,2-DCA was detected in wells K8-01 and K8-04. The 2021 maximum TVOC

concentration of 3.9 µg/L (comprised of 2.8 µg/L of TCE and 1.1 µg/L of 1,2-DCA) was detected in the May duplicate sample from well K8-01, located upgradient of Pit 8 and downgradient of Building 801. The routine sample yielded a TVOC concentration of 3.5 µg/L (2.3 µg/L TCE and 1.2 µg/L 1,2-DCA). These data are similar to historical results.

The historical maximum VOC concentration is 10 µg/L, which was detected four times in samples from well K8-01 between 1988 and 1990 (the most recent collected on February 9, 1990, was comprised of 6 µg/L of TCE and 4 µg/L 1,2-DCA). As in the past, the presence of VOCs in Pit 8 Landfill area wells appears to be a continuation of the VOC plume originating at the Building 801 dry well and is not indicative of a release from the Pit 8 Landfill.

As was the case in 2020 and 2019, groundwater nitrate concentrations in wells K8-01, K8-04, and W-PIT8-3203 exceeded the 45 mg/L MCL cleanup standard during 2021; the maximum 2021 nitrate concentration was 73 mg/L in the May routine sample collected from downgradient detection monitor well K8-04. The duplicate sample yielded 71 mg/L. Well K8-04 also yielded the 2019 maximum nitrate concentration of 71 mg/L.

During the reporting period, other wells exceeding the nitrate MCL of 45 mg/L included well W-PIT8-3203 at 59 mg/L (December) and a duplicate sample from well K8-01 at 47 mg/L (May); the routine sample yielded 44 mg/L. In 2020, the maximum nitrate concentration was 71 mg/L in well K8-04, which also yielded the historical maximum Pit 8 Landfill area nitrate concentration of 80 mg/L in 2015. Overall, area nitrate concentrations are similar to historical results and are not indicative of a new release from Pit 8.

During 2021, wells K8-01 and K8-02B yielded the only detectable tritium activity concentrations in groundwater. Well K8-01 had May detections of 183 ±81.8 pCi/L in a routine sample and 136 ±76.6 pCi/L in a duplicate sample, and December detections of 165 ±79.2 pCi/L in a duplicate sample and 139 ±75.2 pCi/L in a routine sample. Well K8-02B had a December detection of 149 ±41.0 pCi/L in a duplicate sample with no detection exceeding the 100 pCi/L laboratory reporting limit in the paired routine sample, as well as samples collected in May and September. All other wells did not exceed the laboratory reporting limit of 100 pCi/L. The 2020 maximum tritium activity concentration detected in groundwater collected from wells in the Pit 8 Landfill area was 191 ±97.1 pCi/L from well K8-01; the duplicate sample yielded 125 ±41.0 pCi/L. These recent tritium activity concentrations above the reporting limit at well K8-01, which is upgradient of the Pit 8 Landfill, appear to represent the leading edge of the tritium plume that originates at the Building 850 Firing Table.

During 2021, the laboratory reporting limit for perchlorate was changed from 4 µg/L (the typical reporting limit historically and through the first semester of 2021) to 2 µg/L (during the second semester of 2021). During the reporting period, perchlorate was detected in three Building 801/Pit 8 Landfill area wells including:

- Well K8-04 at 7.1 µg/L (exceeding the 6 µg/L MCL cleanup standard for the first time in any Pit 8 detection monitor well) and 4 µg/L in routine and duplicate samples, respectively, in December, and at 4 µg/L and less than the 4 µg/L laboratory reporting limit in duplicate and routine samples in May;
- Well W-PIT8-3203 at 3 µg/L in December and less than the laboratory reporting limit of 4 µg/L in May; and

- Well K8-01 at 2.6 µg/L and 2 µg/L in routine and duplicate samples in December, and less than the laboratory reporting limit of 4 µg/L in May.

Perchlorate was not detected above the typical reporting limit of 4 µg/L (first semester) or 2 µg/L (second semester) in any other wells. During 2020, perchlorate was detected in only one Building 801/Pit 8 Landfill area well, K8-01, at 2.3 µg/L. During 2019, perchlorate was not detected above its reporting limit in any area wells. The aforementioned 7.1 µg/L perchlorate concentration detected in well K8-04 represents the maximum historical perchlorate concentration and was the first time perchlorate was detected above the 6 µg/L MCL cleanup standard for any Pit 8 detection monitor well. Perchlorate concentrations will be closely monitored to identify future trends. The historical distribution of these very low concentrations of perchlorate suggest a past minor release at the former firing table or landfill.

During 2021, well W-PIT8-3203 was the only area well to yield total uranium activity concentrations exceeding the 20 pCi/L MCL cleanup standard at 24 pCi/L in May. Over the previous two years, well W-PIT8-3203 has also been the only area well to exceed the 20 pCi/L MCL cleanup standard at 25 pCi/L (2020) and 23 pCi/L (2019). Total uranium activity concentrations in well W-PIT8-3203 have decreased since the maximum total uranium activity concentration was detected in the area in 2017 (31 pCi/L). The $^{235}U/^{238}U$ atom ratio (0.0073) for the May sample from well W-PIT8-3203 indicated a natural uranium provenance and was consistent with the atom ratio observed in 2017. This was the case for all wells in this area during the reporting period.

During 2021, arsenic concentrations slightly exceeded the MCL cleanup standard of 0.01 mg/L in all five wells sampled in May: W-PIT8-3203 at 0.078 mg/L, K8-04 at 0.027 mg/L, K8-02B at 0.022 mg/L, W-PIT8-3202 at 0.019 mg/L, and W-PIT8-3201 at 0.015 mg/L. During 2020, arsenic concentrations exceeded the MCL cleanup standard of 0.01 mg/L in three wells, W-PIT8-3203 at 0.056 mg/L, K8-04 at 0.023 mg/L, and W-PIT8-3202 at 0.018 mg/L. Since the wells were installed in 2016, groundwater arsenic concentrations have ranged between 0.041 mg/L and 0.078 mg/L in well W-PIT8-3203, and 0.016 mg/L and 0.2 mg/L in well W-PIT8-3202. In well K8-04, from 1989 through 2021, arsenic concentrations have ranged between 0.017 mg/L and 0.030 mg/L, and in well K8-02B ranged between <0.005 mg/L and 0.028 mg/L. Wells W-PIT8-3203, K8-04, and K8-02B (historically), are located along the downgradient edge of Pit 8, while W-PIT8-3202 is located approximately 450 ft northwest and approximately cross-gradient of Pit 8. The reason for these arsenic concentrations slightly in excess of the MCL cleanup standard is unknown, but they are likely natural in origin. Background arsenic concentrations at Site 300 range from 0.002 mg/L to 0.22 mg/L (Ferry et al., 1999). Thus, the arsenic concentrations observed in the Pit 8 wells during 2021 are within the range of background. Arsenic concentrations will be closely monitored during future sampling events.

During 2020, the concentration of nickel in a December groundwater sample from well K8-02B was 0.27 mg/L, exceeding the California state MCL cleanup standard of 0.1 mg/L for nickel; there is no federal MCL cleanup standard for nickel. During 2021, nickel concentrations decreased to 0.032 mg/L, which is below the state MCL. The previous historical maximum nickel detections in this well were 0.02 mg/L (2004), 0.01 mg/L (2005), 0.005 mg/L (2007, 2008, and 2010), and 0.008 mg/L (2009 and 2011); all other historical results for this well have not exceeded the laboratory reporting limit, which ranged from 0.02 mg/L to 0.005 mg/L. Well K8-02B is located approximately 100 ft east

and prior to 2021, generally downgradient, historically, of Pit 8. The reason for the recent nickel concentration increase observed in 2020 at well K8-02B is unknown. Future nickel concentrations in this well will be closely monitored. Nickel concentrations in other Building 801/Pit 8 Landfill area wells did not exceed the laboratory reporting limit during 2021 and have never exceeded the California state MCL cleanup standard of 0.1 mg/L, historically.

Concentrations of other metals (as well as other detection monitoring constituents, including HE compounds, lithium, and fluoride) in samples collected during 2021 from wells upgradient, cross-gradient, and downgradient of the Pit 8 Landfill were either below their cleanup standards or reporting limits, or within the range of background concentrations.

Of the constituents monitored during 2021 as part of the detection monitoring program in $Tnbs_1/Tnbs_0$ HSU groundwater from Pit 8 Landfill area wells, only 1,2-DCA, nitrate, naturally occurring uranium, and arsenic exceeded their federal MCL cleanup standards.

There was no evidence of a new contaminant release from the Pit 8 Landfill indicated by the 2021 groundwater detection monitoring data.

Landfill Inspection Results

During 2021, the Pit 8 Landfill was inspected on January 25, April 7, July 12, and October 13, 2021. No maintenance issues were identified.

Annual Subsidence Monitoring Results

Annual subsidence monitoring was conducted by LLNL during the second semester of 2021. No evidence of subsidence was detected.

Maintenance

No maintenance was necessary at Pit 8 during 2021.

3.5. Pit 9 Landfill

Debris generated at the Building 845 Firing Table was buried in the Pit 9 Landfill from 1958 until 1963. There has been no evidence of contaminant releases from the Pit 9 Landfill.

Sampling and Analysis Plan Modifications

Detection monitoring is conducted in wells located downgradient of the Pit 9 Landfill annually for VOCs, nitrate, tritium, perchlorate, HE compounds, uranium isotopes, metals, lithium, and fluoride. Detection monitor wells for the Pit 9 Landfill include K9-01, K9-02, K9-03, K9-04, W-PIT9-3204, W-PIT9-3205, and W-PIT9-3206.

The sampling and analysis plan for the Pit 9 Landfill groundwater detection monitoring program is presented in Appendix C.

During the first semester of 2021, two of the seven wells, W-PIT9-3205 and W-PIT9-3206, were inaccessible and not sampled, resulting in 16 missed CMP-required analyses. The remaining five wells, K9-01, K9-02, K9-03, K9-04, and W-PIT9-3204 were successfully sampled in accordance with all CMP monitoring requirements. There are no second semester requirements.

Contaminant Detection Monitoring Results

A Building 845 Firing Table and Pit 9 Landfill site map showing building, landfill, and monitor well locations is presented as Figure 2.8-3.

During 2021, arsenic concentrations slightly exceeded the MCL cleanup standard of 0.01 mg/L in one well, K9-02, at 0.018 mg/L (May). The same well yielded an arsenic concentration of 0.056 mg/L in 2020. Since this well was installed in 1989, groundwater arsenic concentrations have ranged between 0.0032 mg/L and 0.056 mg/L. Since 2013, concentrations have shown a slight increasing trend from 0.01 mg/L to 0.03 mg/L in 2019 to 0.056 mg/L in 2020. Well K9-02 is located approximately 25 ft south, and generally cross-gradient of Pit 9. The reason for these arsenic concentrations slightly in excess of the MCL cleanup standard is unknown, but they are likely natural in origin. The observed arsenic concentrations are within background ranges tabulated in the Site-Wide Feasibility Study (Ferry et al., 1999). Future arsenic concentrations will be closely monitored. Arsenic did not exceed the MCL cleanup standard of 0.01 mg/L in the other four wells that were sampled.

Concentrations of other metals, as well as other detection monitoring constituents, including VOCs, nitrate, tritium, perchlorate, HE compounds, uranium isotopes, lithium, and fluoride concentrations/activities in samples collected during 2021 were either below reporting limits or within the range of background concentrations. There was no evidence of a new release from the Pit 9 Landfill during 2021.

Landfill Inspection Results

During 2021, the Pit 9 Landfill was inspected on January 25, April 7, July 12, and October 13, 2021. No maintenance issues were identified.

Annual Subsidence Monitoring Results

Annual subsidence monitoring was conducted by LLNL during the second semester of 2021. No evidence of subsidence was detected.

Maintenance

No maintenance was necessary at Pit 9 during the second semester of 2021.

3.6. Pit 7 Complex Landfills

The Pits 3, 4, 5, and 7 Landfills comprise the Pit 7 Complex. Firing table debris containing tritium, depleted uranium, and metals was placed in the pits in the 1950s through 1989. The Pits 4 and 7 Landfills, and about 30% of Pit 3, were capped in 1991-1992. During years of above-average rainfall (e.g., the 1997-1998 El Niño), groundwater rose into the bottom of the landfills and the underlying contaminated bedrock resulting in the release of tritium, uranium, VOCs, perchlorate, and nitrate to groundwater. In addition to these COCs, groundwater samples from Pit 7 Complex detection monitor wells are also analyzed for metals, HE compounds, and PCBs, as these constituents may exist in the firing table gravels placed in the landfills.

Sampling and Analysis Plan Modifications

Detection monitoring is conducted annually in wells located downgradient of the Pit 7 Landfill Complex for VOCs, nitrate, tritium, perchlorate, HE compounds, uranium isotopes, Title 22 metals, lithium, fluoride, and PCBs.

The sampling and analysis plan for the Pit 7 Complex Landfill groundwater detection monitoring program is presented in Appendix C.

During 2021, one sample for a single requested analyses was not collected at the Pit 7 Complex landfills from monitor well NC7-26 due to wildlife-related access restrictions.

Contaminant Detection Monitoring Results

A map showing the locations of detection monitor wells and the Pit 7 Complex is presented on Figure 2.5-1. Wells K7-01, K7-03, K7-06, K7-09, K7-10, NC7-26, NC7-47, and NC7-48 comprise the current detection monitor well network for the Pit 7 Complex; wells K7-01, K7-03 and NC7-26 are located downgradient of Pit 5 and Pit 7; well K7-06 is upgradient of Pit 7; wells K7-09 and K7-10 are cross-gradient of Pits 3, 5 and 7; well NC7-48 is immediately downgradient of Pit 7; and well NC7-47 is far downgradient of Pits 3 and 7.

The detection monitor wells are screened in the following HSUs:

- NC7-48: Qal/WBR HSU;
- K7-01 and K7-06: Qal/WBR and $Tnbs_1/Tnbs_0$ HSUs;
- K7-03, K7-10, NC7-26 and NC7-47: $Tnbs_1/Tnbs_0$ HSU; and
- K7-09: $Tnsc_0$ HSU.

The 2021 data do not indicate a release of any of the detection monitoring constituents from any of the landfills or underlying vadose zone during the reporting period.

Tritium

The Pits 3 and 5 Landfills have been identified as the sources of previous releases of tritium to groundwater. The Pit 7 Landfill is not an apparent source of tritium in groundwater, as most of the tritium-bearing experiments conducted at Site 300 occurred prior to its opening in 1979 (Taffet et al., 2008).

During 2021, tritium activity concentrations in routine and duplicate groundwater samples collected from Pit 7 Complex detection monitor well K7-03 exceeded the 20,000 pCi/L MCL cleanup standard, with a maximum activity concentration of 36,600 pCi/L (April). Overall, tritium activity concentrations in the Pit 7 Complex detection monitor wells have remained stable between 2020 and 2021.

Uranium

Depleted uranium was previously released to groundwater from Pits 3, 5 and 7 (Taffet et al., 2008). During 2021 none of the Pit 7 detection monitor wells exhibited uranium activity concentrations exceeding the 20 pCi/L MCL cleanup standard. The extent of uranium in Qal/WBR and $Tnbs_1/Tnbs_0$ HSU groundwater is similar to recent years.

Nitrate

Groundwater samples collected during 2021 from Pit 7 Complex detection monitor wells K7-01 and NC7-47 exceeded the 45 mg/L MCL cleanup standard at concentrations of 55 mg/L (May) and 63 mg/L (June), respectively. Groundwater samples from well NC7-47 have never contained any other COCs in excess of background concentrations. Overall, nitrate concentrations in the detection monitor wells have remained stable since 2017.

Perchlorate

Wells K7-01 (screened in both the Qal/WBR and $Tnbs_1/Tnbs_0$ HSUs) and K7-03 (screened in the $Tnbs_1/Tnbs_0$ HSU) are the only detection monitor wells from which groundwater samples have historically yielded perchlorate at concentrations in excess of the 4 µg/L reporting limit. During 2021, only K7-01 contained perchlorate above the reporting limit with 8.1 µg/L (May). Overall, perchlorate concentrations in the detection monitor wells have remained stable or have declined since 2017.

Volatile Organic Compounds

During 2021, TCE was the only VOC detected in the Pit 7 Complex detection monitor well, K7-03 (1.1 µg/L, April). The historical maximum TVOC concentration in samples from monitor well K7-03 was 15.2 µg/L (1985) (composed of 8.7 µg/L of TCE; 0.8 µg/L of PCE; 1.2 µg/L of 1,1,1-TCA; and 4.5 µg/L of 1,2-DCE). VOC concentrations have generally declined in these wells since the 1985 maxima.

Title 22 Metals and Lithium

During 2021, antimony, arsenic, barium, beryllium, cadmium, chromium, cobalt, copper, lead, mercury, molybdenum, nickel, selenium, silver, thallium, vanadium, zinc, and lithium, were not detected in groundwater samples from the Pit 7 Complex detection monitor wells at concentrations in excess of background.

High Explosives Compounds

During 2021, HE compounds were not detected in groundwater samples from the Pit 7 Complex detection monitor wells at concentrations in excess of individual compound detection limits of 1 to 2.5 µg/L.

Polychlorinated Biphenyls

During 2021, PCB compounds were not detected in groundwater samples from the Pit 7 Complex area detection monitor wells at concentrations in excess of the individual compound detection limits of approximately 0.5 µg/L.

Landfill Inspection Results

The Pit 7 Landfill cap annual engineering inspection was performed on March 29, 2021. Inspection results are summarized in the *Pit 7 Cap Annual Engineering Inspection report* (Abri Environmental Engineering, 2021c). The inspection indicated that the cap was in good condition, the vegetation cover was thick and covered the cap, there was no visible erosion, the drainage system was in good condition and appeared to be functioning as intended, and the groundwater monitoring system appeared to be in good condition. LLNL inspections of the Pits 3 and Pit 5 Landfill covers were performed on January 25 and April 7. Results of the inspections indicated that the landfill covers were in good condition.

Annual Subsidence Monitoring Results

Annual subsidence monitoring was conducted during the second semester of 2021. No evidence of subsidence was detected.

Maintenance

Maintenance was performed on the Pit 7 Landfill cap on October 7, 2021, to remove vegetative debris and sediment from the drainage ditch and the dissipator, seal all drainage ditch joints, and fill animal burrows. Maintenance was not required on the Pit 3 or Pit 5 Landfill covers in 2021.

4. Risk and Hazard Management Program

The goal of the Site 300 risk and hazard management program is to protect human health and the environment by controlling exposure to contaminants during remediation. Risk and hazard management is conducted in areas of Site 300 where the exposure point risk exceeded 1×10^{-6} or the hazard index exceeded 1 in the baseline risk assessment. Land use controls have been implemented to manage risks. The CMP/CP requires that the institutional controls in place at Site 300 be evaluated annually (Appendix E).

4.1. Human Health Risk and Hazard Management

The CMP/CP requires that the risk and hazard associated with volatile contaminants in the subsurface that could migrate upward into indoor or outdoor ambient air and be inhaled by workers, where the risk exceeds 1×10^{-6} and hazard index exceeds 1, be reevaluated annually using current data.

The on-site worker inhalation risk associated with VI from the subsurface into indoor and outdoor air is discussed in Section **Error! Reference source not found.**. The on-site worker inhalation risk associated with springs is discussed in Section **Error! Reference source not found.**.

4.1.1. Annual Inhalation Risk Evaluation

Inhalation risk reevaluation for VOCs potentially migrating from the subsurface into indoor air was initiated in 2017 following issuance of revised EPA guidance and ensuing RPM discussions during regulatory review of five-year review documents for Site 300. In 2018 and 2019, DOE/LLNL conducted indoor air sampling within 21 on-site buildings identified as having the highest potential for VOC VI. More than 170 air samples were collected from indoor air, outdoor ambient air, crawl spaces, confined spaces, and areas of preferential pathways. The results of the sampling campaign demonstrated that there is currently no short-term risk to occupants of Site 300 buildings due to VI from subsurface to indoor air, with the exception of Building 833. In 2019, DOE/LLNL deployed an SSDS as part of a mitigative action at Building 833; the SSDS remains operational. Building 833 has not been occupied since 2018 and remained unoccupied in 2021. These results and resultant recommendations were documented in the Addenda to the Five-Year Reviews for all OUs (Demir et. al., 2021a, 2021b, 2021c, 2021d, 2021e, 2021f).

In 2021, DOE/LLNL completed the first year of a new long-term indoor air sampling program in response to these recommendations. The indoor air sampling building prioritization list is included in Appendix F-1. The status of the long-term indoor air sampling program is included in Appendix F-2, Table 1.

DOE/LLNL collected indoor air samples at Site 300 from 11 buildings in 2021. Two sampling events were completed in each building, one during the winter months and one during the summer months, to evaluate the impact of the different weather conditions. A total of 86 air samples were collected from indoor air, crawl spaces, confined spaces, and areas of preferential pathways. Twenty-five outdoor ambient air samples were also collected as part of program. TCE or PCE was detected in 4 of the 11 buildings, however, there were no indoor air screening levels exceedances for PCE or TCE. Sampling event information is summarized in Appendix F-2, Table 1.

The target indoor air concentration screening levels are presented in Appendix F-3, Table 1. The indoor air sampling results for 2021 are included in Attachment 1, Table 3, and are presented in units of ppm_v, as reported by the analytical laboratories, and in units of $\mu g/m^3$, per regulatory request.

Per the Five-Year Review Addenda recommendations, DOE/LLNL developed a contingency plan for additional indoor air sampling in the event that a soil vapor extraction system or VI mitigation system is off-line for more than 30 days. The contingency plan is included in Appendix F-4.

During 2021, all Site 300 soil vapor extraction systems, except 830-SRC and 832-SRC, remained operational and were never off-line for more than 30 days. The 830-SRC SVE system was off-line for more than 30 days during the winter months to protect the facility from freeze damage. Nearby Building 830 was not sampled because the structure is unoccupied and scheduled for demolition. The

832-SRC SVE system was also off-line for more than 30 days. Nearby buildings were not sampled because the initial VI evaluation was completed when the SVE system was off-line. Therefore, additional contingency sampling was not conducted.

DOE/LLNL will continue to implement the long-term sampling program in 2022 and continue to evaluate the potential risk of VI from residual subsurface contamination to indoor air.

4.1.2. Spring Ambient Air Inhalation Risk Evaluation

4.1.2.1. VOC-Contaminated Springs

The CMP requires annual sampling of outdoor air above VOC-contaminated surface water, when present, to determine VOC concentrations.

An unacceptable risk or hazard was identified during the baseline risk assessment (Webster- Scholten, 1994) for the inhalation of VOCs at four locations:

1. Spring 3 (Building 832 Canyon OU) - Cumulative risk of 7×10^{-5}, hazard index of 2.3 due to TCE and PCE;
2. Spring 5 (HEPA OU) - Cumulative risk of 1×10^{-5} due to 1,1-DCE and TCE;
3. Spring 7 (Pit 6 Landfill OU) - Cumulative risk of 4×10^{-5}, hazard index of 1.5 due to TCE, PCE, 1,2-DCA, and CFORM; and
4. The Carnegie SVRA pond (off-site, east of the Pit 6 Landfill) - Cumulative risk 3×10^{-6} (hypothetical) due to TCE.

Spring 3 was sampled on March 9, and August 31, 2021; water samples contained 7.6 µg/L and 1.8 µg/L of TCE, respectively. Spring 5 was visited on March 17 and September 21, 2021; the location was dry during these visits. Spring 7 (BC6-13) was visited on March 3, April 26, August 16, and October 4, 2021; the location was dry during all four visits. Site 300 remains a restricted access, experimental test site. Workers do not work in the vicinity of Spring 3, Spring 5, or Spring 7, except to collect water samples, and spring water is not used for drinking water at the site.

Water-supply well CARNRW2 is used to fill the Carnegie SVRA pond for dust and fire suppression. The baseline risk assessment (Webster- Scholten, 1994) conservatively estimated that if the VOC source in the Pit 6 Landfill was not controlled, contaminated groundwater could migrate to well CARNRW2 and result in an unacceptable risk from inhaling VOC vapors volatilizing from the pond. However, an engineered cap was placed over the Pit 6 Landfill preventing infiltration of precipitation and further releases of contaminants from the landfill. The VOC plume originating from the Pit 6 Landfill continues to not impact CARNRW2 or any groundwater beyond the Site 300 boundary. In 2021, water-supply well CARNRW2 was sampled for VOCs on a monthly basis and VOCs were not detected in excess of reporting limits in any of the samples. Thus, no unacceptable risk or hazard currently exists.

4.1.2.2. Tritium-Contaminated Springs

An unacceptable cumulative risk of 1×10^{-3} was identified in the baseline risk assessment for the inhalation of tritium at the Well 8 Spring in the Building 850 area. This risk was based on the maximum historical tritium activity concentration (770,000 pCi/L, 1972) observed in the spring. Tritium activity concentrations in Well 8 Spring have steadily declined over the decades. The 2009 CMP/CP indicated that the inhalation risk associated with tritium in surface water volatilizing to outdoor ambient air

would be reevaluated annually when surface water is present. Thus, when present, surface water at the Well 8 Spring is sampled and analyzed for tritium annually.

Surface water was last observed at the Well 8 Spring in 2017. The 2017 tritium activity concentration of 6,230 pCi/L in Well 8 Spring was compared to the current preliminary remediation goal (PRG) for tap water obtained using the PRG calculator, as outlined in regulatory guidance (US EPA, 1991). There is no current tritium vapor screening level PRG defined by the EPA for tap water for an outdoor worker. However, the PRG calculator was used to determine a screening level for the inhalation pathway of tritium in tap water using the residential scenario and making site-specific modifications to the exposure parameters in the calculator to determine a PRG for tritium in an on-site spring. This exposure scenario is for an on-site worker who collects a quarterly sample of water at the spring, as this sampler would spend the maximum time at the spring of any individual. The exposure parameters were modified as follows:

1. Remove any child exposure scenarios by using a value of zero for child exposure duration, frequency, and time.
2. Set the exposure parameters for an adult to a duration of 25 years, a frequency of four days a year, and an exposure time of one hour per day.
3. Define an inhalation rate for an adult of 60 cubic meters per hour.
4. Define zero for the number of water intake and bathing events.
5. Define zero for ingestion of produce grown in the vicinity of the spring.

The 2017 activity concentration of tritium in the Well 8 Spring is below the site-specific PRG calculator-derived activity of 9,440 pCi/L for the inhalation pathway of tritium in tap water and well below the MCL drinking water standard of 20,000 pCi/L. From 2018 to 2021, the Well 8 Spring was dry, and no water samples could be collected. The Well 8 Spring was visited on June 9, and October 26, 2021; the location was dry during both visits. Workers will not occupy the site in the near future, site use restrictions will be maintained, and the annual sampling will continue when water is available until the tritium activity concentration remains below acceptable levels for at least two years.

4.2. Ecological Risk and Hazard Management

4.2.1. Ecological Risk and Hazard Management Measures and Contingency Plan Actions Required by the 2009 Compliance Monitoring Report/Contingency Plan

The ecological risk and hazard management measures described in the 2009 CMP/CP (Dibley et al., 2009a) were developed to meet the remedial action objectives for environmental protection. These objectives are designed to:

1. Ensure ecological receptors important at the individual level of ecological organization (special-status species [i.e., State of California or federally-listed threatened or endangered species, or State of California species of special concern]) do not reside in areas where relevant hazard indices exceed 1.
2. Ensure any changes in contaminant conditions do not threaten wildlife populations and vegetation communities.

The ecological risk and hazard management measures required by the 2009 CMP/CP include:

- Periodically evaluate available biological survey data from the Building 801 area, Building 851 area, and the HEPA to determine potential population-level impacts to

ground squirrel and deer exposed to cadmium in surface soil in these areas, as well as reevaluating the ecological hazard associated with cadmium in surface soil in these areas. Subsequent evaluations reported in the 2011 and 2012 Annual CMRs showed the presence of cadmium to no longer be a potential ecological hazard to the deer and ground squirrel populations, or to burrowing or ground-dwelling special-status species. Therefore, cadmium is no longer considered an ecological contaminant of concern in these areas and has been dropped from further consideration.

- Ensure the integrity of the Pit 7 Complex landfill caps to prevent exposure to burrowing animals from uranium.
- Evaluate changes in existing contaminant and ecological conditions in OUs 1 through 8 every five years, which includes reevaluating VOCs in burrow air in the event that groundwater VOC concentrations increase to levels that previously posed a risk to burrowing animals.

This report, and subsequent CMRs prepared during the reporting periods in which the 2009 CMP/CP is active, will continue to provide updates on ecological risk and hazard management measures, and ecological contingency plan actions required by the 2009 CMP/CP.

As part of the contingency plan presented in the 2009 CMP/CP, periodic review of available biological survey data (e.g., biological data collected when surveying ground-disturbing programmatic activities, biological monitoring data, surveys conducted for environmental impact statement [EIS] or environmental impact report [EIR] preparation, etc.) for the presence of new special-status species is required. Any new special-status species identified is to be evaluated for potential impact from the presence of contamination, using the process described in the 2009 CMP/CP. The results of periodic reviews are reported on in the annual CMRs.

As described above, the 2009 CMP/CP requires an evaluation of changes in contaminant and ecological conditions in OUs 1 through 8 every five years. Five-year ecological reviews were conducted in 2008 (reported in Dibley et al., 2009b; referred to as the 2008 Five-Year Ecological Review); 2013 (reported in Dibley et al., 2014; referred to as the 2013 Five-Year Ecological Review); and 2018 (reported in Buscheck et al., 2019; referred to as the 2018 Five-Year Ecological Review). The 2008 Five-Year Ecological Review evaluated chemical data collected from January 1, 1999, through December 31, 2007, and ecological data collected from January 1, 1999, through December 31, 2008. The 2013 Five-Year Ecological Review evaluated chemical data collected from January 1, 2008, through December 31, 2012, and biological data collected between January 1, 2009, and December 31, 2012 (four years of biological data). The 2018 Five-Year Ecological Review evaluated chemical and biological data collected between January 1, 2013, and December 31, 2017.

The 2008 Five-Year Ecological Review identified several new constituents in surface water for which ecological hazard could not be adequately evaluated due to either a limited data set or the lack of background data. Most of these constituents have been addressed and reported in CMRs subsequent to the 2008 Five-Year Ecological Review. The remaining constituents were also noted in the 2013 and 2018 Five-Year Ecological Reviews and are further discussed below.

4.2.2. Uranium in Subsurface Soil within the Pit 7 Complex Landfills

The 2009 CMP/CP requires that the Pit 7 Complex landfills be inspected. Any burrows or holes in the cover must be filled to prevent unacceptable exposure of animals to uranium in the pit waste. This

is done as part of the inspection and maintenance program for the Pit 7 Complex. Section 3.4 describes the landfill annual engineering inspection results, the annual subsidence monitoring results, and any maintenance that was performed. The annual engineering inspection of the Pit 7 cap conducted by Abri Environmental Engineering in June 2020 (Abri Environmental Engineering, Inc., 2021c) found the cap to be in good condition and the vegetation cover to be thick and covering the cap with no visible erosion. Some recent animal burrows were observed. Inspections of the Pits 3 and 5 covers were conducted by LLNL on January 25 and April 7, 2021. Results from the inspections indicated that the landfill covers are in good condition.

4.2.3. Identification and Evaluation of New Special-Status Species

Contingency actions described in the 2009 CMP/CP include periodically evaluating available biological survey data (e.g., from pre-construction surveys, biological monitoring, and surveys conducted for EIR/EIS preparation) for the presence of new special-status species and reporting the results of the evaluation in the annual CMRs. The results of biological surveys and any changes in the regulatory status of species occurring at Site 300 in 2021, as determined by DOE/LLNL wildlife biologists, are discussed below.

In 2021, routine monitoring surveys were conducted at Site 300 for California red-legged frogs, California tiger salamanders, western burrowing owls, nesting raptors, tricolored blackbirds, and rare plants. These species continue to occur in areas and habitat, as described in the 2018 Five-Year Ecological Review (Buscheck et al., 2019). Pools M1a and M1b continue to be the most successful, consistent California red-legged frog breeding habitat at Site 300. However, extreme drought conditions during the 2020-2021 winter impacted the breeding success of California red-legged frogs at Site 300. No evidence of California red-legged frog reproduction was observed at Site 300 in 2021.

Although year-to-year variations in the suitability of Site 300 seasonal pools for California tiger salamander and California red-legged frog breeding is normal, Site 300 amphibians are particularly vulnerable to changes in rainfall patterns because they rely on seasonal pools that are only expected to fill with water during years of average or greater rainfall. Several seasonal pools that provide breeding habitat for the California tiger salamander and California red-legged frog at Site 300 did not fill in 2021. California tiger salamander eggs were observed in 2021 in Pool OS and a concrete v-ditch that is part of the Pit 7 Landfill cap drainage system. The remaining Site 300 seasonal pools (Pools A, H, M2, HC1, S, M3, and Lower and Upper D) did not fill in 2021 due to drought conditions. Therefore, California tiger salamanders were not able to reproduce in these locations. None of the pools, including Pool OS, remained inundated long enough for California tiger salamander metamorphosis.

Surveys to determine the location and success of nesting pairs of western burrowing owls were conducted throughout Site 300 in the spring and summer of 2021. Seven pairs of nesting burrowing owls were observed throughout areas at Site 300 previously used by this species.

Surveys for nesting raptors other than western burrowing owls were conducted at Site 300 and within the Corral Hollow Creek riparian corridor in the spring and summer of 2021. Although no Swainson's hawks were observed nesting during these surveys, wildlife biologists observed Swainson's hawks foraging over the northern half of Site 300 during the summer of 2021. Common raptor species, including red-tailed hawks, were observed nesting at Site 300 in 2021.

LLNL biologists annually track a nesting tricolored blackbird colony at Site 300. Tricolored blackbirds *(Agelaius tricolor)* are listed as threatened under the California Endangered Species Act

and as protected by the federal Migratory Bird Treaty Act. This species occurs in colonies that travel seasonally between nesting and foraging habitat. Tricolored blackbirds are known to nest within wetland habitat in Elk Ravine both upstream and downstream of Building 812 and occasionally in a small, isolated wetland north of Elk Ravine. The tricolored blackbird colony was observed at Site 300 in 2021 arriving in mid-March and remaining onsite until mid-May. The colony continued to be very small with less than 500 tricolored blackbirds observed within Elk Ravine in 2021.

Routine biological surveys conducted in 2021 included pre-activity surveys conducted prior to fire trail grading. Approximately 85 miles of dirt fire trails are graded annually at Site 300. Fire trail surveys are conducted each spring in preparation for annual fire trail grading. During fire trail surveys, LLNL wildlife biologists traverse all Site 300 fire trails in a 6-wheeled off-road vehicle or a 4-wheel drive truck. Stops are made at vantage points or sensitive habitat features and surveys are performed with binoculars or on foot. Biologists typically search for burrows that can provide habitat for protected species (California red-legged frogs, California tiger salamanders, badger, and burrowing owls) and nesting birds. Other special status species are noted when observed. Observations of Blainsville's horned lizards and American badger during fire trail surveys show that these two California Special Status Species occurred in several areas throughout Site 300 in 2021.

4.2.4. Constituents Identified in Five-Year Ecological Reviews Requiring Additional Monitoring

The 2018 Five-Year Ecological Review identified several constituents in surface soil and subsurface soil for which data were not sufficient to determine potential ecological hazard. Ecological Screening Levels were exceeded for several metals and radionuclides present in surface and subsurface soil samples collected in the northeast corner of Site 300 and the Building 851 area. Sampling was conducted in the northeast corner of Site 300 as part of the project to determine background concentrations of metals and radionuclides in soil. Sampling was conducted in the Building 851 area as part of an investigation of constituents in local soil. Both efforts are ongoing. Ecological hazards from metals and radionuclides in the Building 851 soil will be determined when updated background concentrations for metals and radionuclides are established.

With the exception of perchlorate in the Well 8 Spring, no significant changes in COC concentrations were identified in the 2018 Five-Year Ecological Review in the Site 300 springs located in the OUs covered by the 2009 CMP/CP. However, several constituents identified in the 2013 Five-Year Ecological Review for which data were not sufficient to determine potential ecological hazard were also noted as such in the 2018 Five-Year Ecological Review.

Perchlorate in the Well 8 Spring (Building 850 portion of OU 5, Figure 2.5-1) was found to pose a risk to the aquatic life stage of amphibian species in the *Building 850 Focused RI/FS for Perchlorate* (Verce et al., 2019). While the spring does not currently support breeding habitat for amphibians, it is located in an area used by special-status amphibian species (California tiger salamander and California red-legged frog). To support the evaluation of potential risk from perchlorate in the Well 8 Spring, monitoring of the spring for the presence of amphibian breeding habitat and special-status amphibians was added to the ecological risk and hazard management program in 2021, in time for the 2023 Five-Year Ecological Review.

Uranium in Springs 10 and 11 (Building 854 OU, Figure 2.6-1) was identified in the 2013 Five-Year Ecological Review as a constituent for which data were not sufficient to determine potential

ecological hazard. While uranium activity concentrations in Spring 11 were not more than 50% greater than those detected in review periods previous to 2013, they were greater than the Site 300 background level, and uranium concentrations (as mg/L) were greater than the ecological screening level established for the Building 812 ecological risk assessment (Carlsen et al., 2012). The maximum total uranium concentration in Spring 10 and Spring 11 exceeded the Site 300 background concentration in the June 2002 (Spring 11) and the June 2003 (Spring 10) samples. Both samples were analyzed for uranium isotopes using mass spectrometry, and results from both springs showed a natural $^{235}U/^{238}U$ atom ratio of 0.0072. Spring 11 was sampled in August 2012 and contained a high concentration of uranium (0.074 mg/L). The $^{235}U/^{238}U$ atom ratio of 0.0072 indicated natural uranium. Spring 10 was dry at this time and remained dry through the 2019 review period. Due to limitations on personnel during the COVID-19 pandemic shelter-in-place, Springs 10 and 11 were only accessed once in 2020 (December) and were both again dry. The original location of Spring 11 was buried by a mudslide a few years ago. The new location is south of the original location where there is, at best, only damp soil observed when accessed. The Site 300 previous maximum background concentration was 0.028 mg/L, detected in Spring 16. The natural $^{235}U/^{238}U$ atom ratios in samples collected from the Springs 10 and 11 indicate that these uranium concentrations, though elevated, likely represent background conditions. Uranium concentrations will be periodically monitored in these springs when and if water is present to sample.

Chloride in Spring 14 (HEPA OU, Figure 2.4-1) was identified in the 2013 Five-Year Ecological Review as a constituent for which data were not sufficient to determine potential ecological hazard. The historical chloride concentrations detected in Spring 14 in samples collected through May 2001 (ranging from 160 mg/L to 420 mg/L) periodically exceeded the maximum concentration observed in Site 300 background springs (210 mg/L). However, the chloride concentrations in the two most recent samples (collected in December 2003 and March 2013) contained chloride concentrations at or below this background level (170 mg/L and 210 mg/L, respectively). While it appears that chloride in Spring 14 is not of ecological concern, chloride concentrations in this spring will be periodically monitored when water is available to ensure concentrations remain within background levels. This spring was inaccessible in 2017 and 2019 due to overgrown vegetation conditions and has otherwise been dry since 2015. DOE/LLNL will attempt to sample the spring in 2021.

The 2013 Five-Year Ecological Review also identified total phosphorus (as P) and ammonia nitrogen in Spring 4 (Building 832 Canyon OU, Figure 2.7-1) as constituents for which data were not sufficient to determine potential ecological hazard. The single sample from Spring 4 analyzed for total phosphorus (4 mg/L, June 2000) exceeded the maximum concentration of total phosphorus observed in the Site 300 background springs (0.3 mg/L). The maximum concentration of ammonia nitrogen (8.7 mg/L) in Spring 4 was also detected in the June 2000 sample, which is the most recent sample available that was analyzed for this constituent. Spring 17, a Site 300 background spring, was sampled for ammonia nitrogen during the review period for the 2013 Five-Year Ecological Review (August 2012). Ammonia nitrogen was detected in Spring 17 in 2012 (during that review period) at a concentration of 0.52 mg/L. Spring 4 has been dry since 2007 (and was again dry in 2019 and 2020 when accessed). Spring 4 will be periodically sampled for ammonia nitrogen and total phosphorus when water is available to provide additional data on these constituents.

5. Data Management Program

The management of data collected during the second semester of 2021 was subject to internal data management process and standard operating procedures (SOPs) (Goodrich and Lorega, 2016). This data management process uses a relational database to track sample and analytical information from an initial sampling plan through data storage and reporting. Per the SOPs for data quality, this process includes sample planning, chain of custody tracking, sample collection history, electronic and hard copy analytical results receipt, strict data validation and verification, data quality control procedures, and data retrieval and presentation. Data management and data retrieval is facilitated by a web-based system known as The Environmental Information Management System (TEIMS). The use of this system promotes and provides a consistent data set of known quality. Quality assurance and quality control are performed regularly on all data.

5.1. Modifications to Existing Procedures

The relational database used to maintain the data for the CMR is Oracle. During the second semester of 2021 it was upgraded from version 12.1.0.2 to version 19.11.2.0.0. Simultaneously with the Oracle upgrade, the Linux systems and software applications were updated to consistently use Oracle Instant Client as the Oracle connection library. The operating system is Linux RHEL 7.9. General maintenance and refinements continued in both the database and the web application programming. Improvements and additions to the data management process are continuously implemented in an ongoing effort to automate and upgrade the applications. The following improvements and rearchitected web tools were released during the reporting period:

- Entry of well screen material and well screen type was modified. Valid values lists were created, and foreign keys were applied to ensure consistency.
- The Air Quality Management report was improved in several ways. The calculation for "Operational Days Since Previous Sample" was improved to display the number of operational days since the last actual reading and to include any new operational time. All treatment facilities with air permits are now included regardless of status.
- Treatment Facility (TF) Reference Tool data was extended to identify additional staff positions as well as backup staff, and the online help was improved to define the different "active" values.
- The requirements for the Oracle password used to connect to the database were updated to be consistent with the institutional password requirements.
- The Field Location Tool received several enhancements to the user interface that facilitate faster data entry for new locations, including improved display of fields for data entry.

5.2. New Procedures

The process of rearchitecting existing computer programs that generate data-driven web pages continues, with the dual goals of improving maintainability and user efficiency. Foundational infrastructure code is being updated from the programming language Perl to Python, and the user interface and webpage capabilities are being improved.

Many software development processes and procedures have been implemented as part of the rearchitecture effort:

- Underlying software architecture upgrades are more service-oriented. Common functionalities have been encapsulated into independent services to increase code reusability and maintainability, allowing individual services to be changed/upgraded with minimal disruption to the rest of the system.
- Static analysis is being included for early identification of syntax and other errors. This improvement is incorporated into integrated developer environments (IDE) and is also performed automatically as a prerequisite to any code being checked into production-bound code repositories.
- Software development standards have been developed to promote consistency among all components to reduce the overall system maintenance burden.
- There is now an enforced requirement to develop software-based tests to accomplish unit, functional, integration, and regression testing. Test coverage metrics are tracked per component, per application, and for the overall system with a coverage target of above 80%.
- All software code undergoes peer review prior to being incorporated into production bound code repositories.
- All applications undergo multiple reviews by users and customers prior to production release, and web tools are beta-tested prior to formal release.

New web tools were released. These tools include:

- A new borehole logging tool that allows users to input lithology depth intervals was released. Helpful features of the tool include automatically placing the cursor in the field to enter the depth, real time validation, and once submitted, a confirmation email is sent.
- The Total Uranium tool was released with the ability to look up isotopic or total uranium groundwater sample data and find the calculated total uranium and individual isotope activity concentration data for each sample.
- An Advanced Search feature was added allowing users to add search criteria, indicating how many records will be returned by the search, and allowing user to see results in advance so they can add more filters for greater specificity, if desired.
- The Account Request tool was released replacing an older version, allowing users to submit requests for new user accounts, track tasks associated with setting up a new account, and giving requesters the ability to select what type of account the new user should have.

7. Acronyms and Abbreviations

1,1-DCA	1,1-Dichloroethane
1,2-DCA	1,2-Dichloroethane
1,1-DCE	1,1-Dichloroethene
1,2-DCE	1,2-Dichloroethene (total)
1,1,1-TCA	1,1,1-Trichloroethane
1,1,2-TCA	1,1,2-Trichloroethane
2-ADNT	2-Amino-4,6-dinitrotoluene
4-ADNT	4-Amino-2,6-dinitrotoluene
815	Building 815
817	Building 817
829	Building 829
830	Building 830
832	Building 832
834	Building 834
845	Building 845
850	Building 850
851	Building 851
854	Building 854
A	Annual
amsl	Above mean sea level
AS	Alpha spectrometry
As N	As nitrogen
As $CaCO_3$	As calcium carbonate
BA	Blanket agreement
BGS	Below ground surface
BTEX	Benzene, toluene, ethyl benzene, and xylene
°C	Degrees Celsius
C12-C24	Diesel range organic compounds in the 12 carbon to 24 carbon range
CAL	Contracted analytical laboratories
CAMU	Corrective Action Management Unit
CAP	Corrective and Preventative Action Program
CERCLA	Comprehensive Environmental Response, Compensation and Liability Act
cf	Cubic feet
cfm	Cubic feet per minute
CFORM	Chloroform
CGSA	Central General Services Area
CHC	Corral Hollow Creek
cis-1,2-DCE	*cis*-1,2-Dichloroethene
CMP/CP	Compliance Monitoring Plan/Contingency Plan
CMR	Compliance Monitoring Report
CO_2	Carbon dioxide

COC	Contaminant of Concern
CTA	Cleanup Time Analysis
CTET	Carbon tetrachloride
DDS	Drainage Diversion System
DIS	Discretionary sampling (not required by the CMP)
DISS	Distal south
DMW	Detection monitor well
DNAPL	Dense non-aqueous-phase liquid
DO	Dissolved oxygen
DOE	Department of Energy
DOECAP	Department of Energy Consolidated Audit Program
DSB	Distal Site Boundary
DTSC	Department of Toxic Substances Control
DUP	Duplicate or collocated QC sample
E	Effluent (acronym found in Treatment Facility Sampling Plan Tables)
E	Sample to be collected during even numbered years (i.e., 2016) (acronym found in Sampling Plan Tables)
EcoSSLs	Ecological Soil Screening Levels
EFA	Environmental Functional Area
EGSA	Eastern General Services Area
EIS/EIR	Environmental Impact Statement/Environmental Impact Report
EMS	Environmental Management System
EPA	Environmental Protection Agency
ES&H	Environmental Safety and Health
EV	Effluent vapor
EW	Extraction well
FEFLOW	Finite Element subsurface FLOW system
Freon 11	Trichlorofluoromethane
Freon 113	1,1,2-trichloro-1,2,2-trifluoroethane
ft	Feet
ft^3	Cubic feet
FY	Fiscal year
g	Gram(s)
GAC	Granular activated carbon
gal	Gallon(s)
GIS	Geographic Information Systems
gpd	Gallons per day
gpm	Gallons per minute
GSA	General Services Area
GTU	Groundwater Treatment Unit.
GW	Guard well
GWES	Groundwater extraction system

GWTS	Groundwater treatment system
GW-ADV	Groundwater to indoor air pathway, advanced version
HE	High Explosives
HEPA	High Explosives Process Area
HMX	High-Melting Explosive
HQ	Hazard quotient
HSU	Hydrostratigraphic unit
I	Influent
ICP-MS	Inductively Coupled Plasma - Mass Spectrometry
IDE	Integrated developer environments
inHg	Inches of mercury
ISMA	*In Situ* Microcosm Array
ISMS	Integrated Safety Management System
ISO	International Organization for Standardization
ITS	Issues Tracking System
IV	Influent vapor
IW	Injection well
IWS	Integrated Work Sheet
JEM	Johnson and Ettinger Model
K-40	Potassium-40
KB-1™	A consortium of dechlorinating bacteria that contain *Dehalococcoides ethenogenes*
kft^3	Thousands of cubic feet
kg	Kilograms
kgal	Thousands of gallons
KPA	Kinetic Phosphorescence Analysis
LAS	The Lidar Base Specification from the National Geospatial Program for file formats
LCS	Laboratory Control Sample
LHC	Light hydrocarbon
LLNL	Lawrence Livermore National Laboratory
LLNS	Lawrence Livermore National Security
LNAPL	Light non-aqueous-phase liquid
µg/L	Micrograms per liter
$\mu g/m^3$	Micrograms per meters cubed
µmhos/cm	Micro ohms per centimeter
µS	Microsiemens
M	Monthly
MCL	Maximum Contaminant Level
MeCL	Methylene chloride
Mgal	Millions of gallons
Mg/kg/d	Milligram per kilogram per day

mg/L	Milligrams per liter
MNA	Monitored natural attenuation
MS	Mass spectrometry
MSA	Mean Sea Level
mV	Millivolts
MWB	Monitor well used for background
N	No
NB	Nitrobenzene
N_2	Nitrogen gas
NO_3	Nitrate
NA	Not applicable
NT	Nitrotoluene
NTU	Nephelometric turbidity units
O	Sample to be collected during odd numbered years (i.e., 2015)
OR	Occurrence Report
ORP	Oxidation/reduction potential
OU	Operable unit
O&M	Operations and Maintenance
P/PO_4	Phosphorus/Phosphate ion
PBA	Programmatic Biological Assessment
PCBs	Polychlorinated biphenyls
PCE	Tetrachloroethene
pCi/L	PicoCuries per liter
pH	A measure of the acidity or alkalinity of an aqueous solution
ppb_v	Parts per billion by volume
$ppm_{v/v}$	Parts per million on a volume-to-volume basis
PPCP	Pharmaceutical and Personal Care Product analytes
PRG	Preliminary remediation goal
PRX	Proximal
PRXN	Proximal north
PTU	Portable Treatment Unit
PVC	Polyvinyl chloride
Q	Quarterly
Qal	Quaternary alluvium
QA/QC	Quality assurance/quality control
QC	Quality control
QIF	Quality Improvement Form
RAOs	Remedial Action Objectives
R1	Receiving water sampling point located 100 ft upstream
R2	Receiving water sampling point located 100 ft downstream
RCRA	Resource Conservation and Recovery Act
RD	Remedial Design

RDX	Research Department Explosive
REA	Reanalysis
Redox	Reduction-oxidation reaction
REVAL	Remediation Evaluation Process
REX	Resample
RHEL	Red Hat® Enterprise Linux®
RI/FS	Remedial Investigation/Feasibility Study
ROD	Record of Decision
ROI	Radius of influence
RPM	Remedial Project Manager
RWQCB	Regional Water Quality Control Board
S	Semi-annual
scfm	Standard cubic feet per minute
SJVAPCD	San Joaquin Valley Air Pollution Control District
SLs	Statistical limits
SOP	Standard Operating Procedure
SPACT	Sample Planning and Chain of Custody Tracking
SPR	Spring
SRC	Source
STFCS	Standard treatment facility control system
STU	Solar-powered Treatment Unit
SVE	Soil Vapor Extraction
SVTS	Soil Vapor Treatment System
SVI	Soil Vapor Influent
SVRA	State Vehicular Recreation Area (Carnegie)
SWEIS	Site-Wide Environmental Impact Statement
SWRESR	Site-Wide Remediation Evaluation Summary Report
SWFS	Site Wide Feasibility Study
SWPPP	Storm Water Pollution Prevention Program
SWRI	Site-Wide Remedial Investigation
T2	Study Area Within the Distal Area of Building 834
TBOS	Tetrabutyl orthosilicate
TCE	Trichloroethene
TCEP	tris (2-chloroethyl) phosphate
TDS	Total dissolved solids
TEIMS	The Environmental Information Management System
TF	Treatment facility
TFRT	Treatment Facility Real Time
THMs	Trihalomethanes
TKEBS	Tetrakis (2-ethylbutyl) silane
TNB	Trinitrobenzene
TNT	Trinitrotoluene

Total-1,2-DCE	1,2-Dichloroethene (total)
trans-1,2-DCE	*trans*-1,2-dichloroethene
TRV	Toxicity Reference Value
TVOC	Total volatile organic compounds
TWA	Time-weighted average
t-1,2-DCE	*trans*-1,2-Dichloroethene
$^{235}U/^{238}U$	Atom ratio of the isotopes uranium-235 and uranium-238
U.S.	United States
VC	Vinyl chloride
VCF4I	Fourth vapor phase granular activated carbon filter influent
VE	Vapor effluent
VES	Vapor extraction system
VI	Vapor intrusion
VISL	Vapor Intrusion Screening Level
VOC	Volatile organic compound
WAA	Waste accumulation area
WBR	Weathered bedrock
WDR	Waste Discharge Requirements (Program)
WGMG	Water Guidance and Monitoring Group
WP&C	Institutional-Wide Work Planning and Control
WS	Water supply well
Y	Yes

Stratigraphic Units

Qal =	Quaternary alluvium.
Qls =	Quaternary landslide deposits.
Qt =	Quaternary terrace deposits.
WBR =	Weathered bedrock.
Tps =	Pliocene non-marine unit.
Tpsg =	Pliocene non-marine unit (gravel facies).
$Tnsc_2$ =	Miocene Neroly Formation upper siltstone/claystone.
$Tnbs_2$ =	Miocene Neroly Formation upper blue sandstone.
$Tnsc_{1a}$, $Tnsc_{1b}$, $Tnsc_{1c}$ =	Sandstone bodies within the $Tnsc_1$ Neroly Formation middle siltstone/claystone ($Tnsc_1$) (1a = deepest).
$Tnbs_1$ =	Neroly Formation lower blue sandstone.
Upper $Tnbs_1$ ($UTnbs_1$) =	Upper member of the Neroly Formation lower blue sandstone, above claystone marker bed.
Lower $Tnbs_1$ =	Lower member of the Neroly Formation lower blue sandstone, below claystone marker bed (regional aquifer).
$Tnbs_0$ =	Neroly Formation basal sandstone.
$Tnsc_0$ =	Miocene Neroly Formation lower siltstone/claystone.
Tmss =	Miocene Cierbo Formation.
Tts =	Eocene Tesla Formation.

Data Qualifier Flag Definitions

B = Analyte found in method blank, sample results should be evaluated.
D = Analysis performed at a secondary dilution or concentration.
E = The analyte was detected below the LLNL reporting limit, but above the analytical laboratory minimum detection limit.
F = Analyte found in field blank, trip blank, or equipment blank.
G = Quantitated using fuel calibration but does not match typical fuel fingerprint.
H = Sample analyzed outside of holding time, sample results should be evaluated.
I = Surrogate recoveries were outside of QC limits.
J = Analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample.
L = Spike accuracy not within control limits.
O = Duplicate spike or sample precision not within control limits.
R = Sample results are rejected due to serious deficiencies in the ability to analyze the sample and meet quality control criteria. The presence or absence of the analyte cannot be verified.
S = Analytical results are rejected due to serious deficiencies in the ability to analyze the sample and meet QC criteria. The presence or absence of the analyte cannot be verified.
T = Analyte is tentatively identified compound; result is approximate.

Table Summ-1. Mass removed, January through December 2021.

Treatment Facility	Volume treated		Estimated total mass removed					
	Groundwater (Kgal)	Soil vapor (Kcf)	VOC (g)	Perchlorate (g)	Nitrate (kg)	RDX (g)	TBOS/TKEBS (g)	Uranium (g)

Notes:
- = Not applicable
CGSA = Central General Services Area
CGSA-N = Central General Services Area North
DIS = Distal
DISS = Distal south
DSB = Distal site boundary
g = Grams
GWES = Groundwater Extraction System
GWTS = Groundwater Treatment System HSU = Hydrostratigraphic unit
Kcf = Thousands of cubic feet
Kgal = Thousands of gallons
PRX = Proximal
RDX = Research Department Explosive
SRC = Source
SVTS = Soil Vapor Treatement System
TBOS = Tetra 2-ethylbutylorthosilicate
TKEBS = Tetrakis (2-ethylbutyl) silane
VOC = Volatile organic compound

Nitrate reinjected into the $Tnbs_2$ HSU undergoes in-situ biotransformation to benign N_2 gas by anaerobic denitrifying bacteria. Nitrate mass removal is calculated assuming complete removal of nitrate from treated groundwater. At Pit 7, reinjected effluent may contain nitrate concentrations below the discharge limit but above the detection limit. Thus, nitrate mass removal calculations at Pit 7 are overestimated.

Table Summ-2. Summary of cumulative remediation through December 2021.

Nitrate reinjected into the $Tnbs_2$ HSU undergoes in-situ biotransformation to benign N_2 gas by anaerobic denitrifying bacteria. Nitrate mass removal is calculated assuming complete removal of nitrate from treated groundwater. At Pit 7, reinjected effluent may contain nitrate concentrations below the discharge limit but above the detection limit. Thus, nitrate mass removal calculations at Pit 7 are overestimated.

Table 2.4. Concentrations and activity concentrations of contaminants of concern in groundwater extraction and treatment system influent and effluent, July through December 2021.

Table 2.4. Concentrations and activity concentrations of contaminants of concern in groundwater extraction and treatment system influent and effluent, July through December 2021.

Location	Period	Date Sampled	1,1,1-TCA (ug/L)	1,1,2-TCA (ug/L)	1,1-DCA (ug/L)	1,1-DCE (ug/L)	1,2-DCA (ug/L)	CTET (ug/L)	CFORM (ug/L)	Freon 113 (ug/L)	PCE (ug/L)	TCE (ug/L)	Freon 11 (ug/L)	VC (ug/L)	cis-1,2-DCE (ug/L)	trans-1,2-DCE (ug/L)	Nitrate (as NO3) (mg/L)	ClO4 (ug/L)	HMX (ug/L)	RDX (ug/L)	4-Amino 2,6-DNT (ug/L)	TBOS/ TKEBS (ug/L)	3H (pCi/L)	Total Uranium (AS) (pCi/L)

[a] No samples collected. System off-line for freeze protection.
[b] Only influent samples collected; extracted water to be treated at another facility.
[c] System off-line due to equipment failure.
[d] Additional samples were collected to verify treatment media performance.
[e] Facility secured to resolve treatment media performance issues.
[f] Facility secured to prevent equipment damage during construction activities on Pit 7 Road.
[g] Nitrate effluent monitoring not required; influent nitrate samples collected for treatment media management purposes.
[h] System off-line for construction.

Notes:
- = Not a contaminant of concern for this operable unit or sampling not required
AS = Alpha Spectrometry
D = Analysis performed at a secondary dilution or concentration.
L = Matrix spike recoveries not within control limits.

Table 2.5. 2021 annual summary of treatment facility operations.

OU	Treatment facility	Operated?	In compliance?	Facility highlights
OU 1	**CGSA GWTS**	Yes	Yes	• Facility remained secured from January 1 to April 12 for freeze protection. • Facility was secured from April 12 to June 7 after an attempted restart following freeze protection and remained secured due to equipment issues. • Facility was secured from June 10 to June 16 due to equipment issues. • Facility shut down from July 2 to July 6 due to a power outage. • Facility was secured from July 15 to July 19 due to a planned power outage. • Facility was secured from August 21 to August 25 due to a planned power outage. • Facility was secured from November 17 to the end of the reporting period for freeze protection.
	CGSA SVTS	Yes	Yes	• Facility shut down from July 2 to July 6 due to a power outage. • Facility was secured from July 15 to July 19 due a planned power outage. • Facility shut down from July 23 to July 26 due control system interlock. • Facility was secured from August 21 to August 25 due a planned power outage.
	CGSA-N GWES	Yes	Yes	• Facility remained secured from January 1 until June 8 for freeze protection and due to the shutdown of the CGSA GWTS which treats groundwater from the GWES. • Facility shut down from July 2 to July 6 due to a power outage. • Facility was secured from July 8 to July 12 due a planned power outage. • Facility was secured July 15 to July 19 due a planned power outage. • Facility was secured from August 21 to August 25 due to control system interlock and planned power outage. • Facility shut down from September 14 to September 30 due to equipment issues. • Facility was secured from October 14 to October 18 for a sampling event. • Facility was secured from November 8 to the end of the reporting period for freeze protection.
OU 2	**834 GWTS**	Yes	Yes	• Facility remained secured from January 1 until April 12 for freeze protection. • Facility was secured from May 4 to August 4 due to equipment issues. • Facility was secured from November 15 to the end of the reporting period for freeze protection.
	834 SVTS	Yes	Yes	• None.
OU 4	**815-SRC GWTS**	Yes	Yes	• Extraction well W-815-2803 remained secured from January 1 to March 10 for freeze protection.

Table 2.5. 2021 annual summary of treatment facility operations.

OU	Treatment facility	Operated?	In compliance?	Facility highlights
				• Facility was secured from June 4 to June 8 due to a control system issue. • Extraction well W-815-2803 was secured from November 15 to the end of the reporting period for freeze protection. • Extraction well W-815-04 was secured from December 6 to the end of the reporting period for freeze protection.
	815-PRX GWTS	Yes	Yes	• Extraction well W-818-08 was secured from April 26 to December 13 for equipment issues.
	815-DSB GWTS	Yes	Yes	• Facility remained secured for freeze protection from January 1 to March 9. • Facility was secured from November 12 to the end of the reporting period for freeze protection.
	817-SRC GWES	Yes	Yes	• Facility remained secured from January 1 to July 21 for freeze protection and upgrade activities.
	817-PRX GWTS	Yes	Yes	• Extraction well W-817-2318 remained secured for freeze protection from January 1 to May 3. • Facility was secured from April 30 to May 3 due to treatment media changeout. • Facility was secured from August 13 to October 4 due to treatment media performance issues. • Extraction well W-817-2318 was secured from November 18 to the end of the reporting period for freeze protection; the facility continued to operate using extraction well W-817-03.
	829-SRC GWES	Yes	Yes	• Facility remained secured for freeze protection from January 1 to March 25. • The facility was secured from November 8 to the end of the reporting period for freeze protection.
OU 5	**PIT7-SRC GWTS**	Yes	Yes	• Facility was secured from January 7 to January 11 for a planned power outage. • Facility was secured from April 22 to April 28 due to communication system issues. • Facility was secured from June 1 to June 7 for control system issues. • Facility was secured from August 30 to the end of the reporting period to prevent equipment damage during construction activities on Pit 7 Road.
OU 6	**854-SRC GWTS**	Yes	Yes	• Facility remained secured from January 1 to April 6 for freeze protection. • Facility was secured from May 6 to May 10 due to a planned power outage. • Facility shut down from May 21 to May 24 due to a power outage. • Facility shut down from July 15 to July 19 due to control system issues.

Table 2.5. 2021 annual summary of treatment facility operations.

OU	Treatment facility	Operated?	In compliance?	Facility highlights
				• Facility was secured from August 12 to August 23 due to control system software upgrades. • Facility was secured from November 16 to the end of the reporting period for freeze protection.
	854-SRC SVTS	Yes	Yes	• Facility was secured from May 6 to May 10 due to a planned power outage. • Facility shut down from May 21 to May 24 due to a power outage. • Facility was secured from August 11 to August 17 due to treatment media changeout.
	854-PRX GWTS	Yes	Yes	• Facility was secured from May 6 to May 10 due to a planned power outage. • Facility shut down from May 21 to May 24 due to a power outage.
	854-DIS GWES	Yes	Yes	• Facility operated at a lower capacity from January 1 to June 24 due to controls system issues. • Facility was secured from June 24 to the end of the reporting period due to engineering upgrades to the controls and data collection system.
OU 7	**832-SRC GWTS**	Yes	Yes	• Facility remained secured from January 1 to October 19 for upgrades. • Facility was secured from October 28 to November 1 due to a planned power outage. • Facility was secured from November 22 to the end of the reporting period for freeze protection.
	832-SRC SVTS	Yes	Yes	• Facility remained secured from January 1 to October 20 for upgrades. • Facility was secured from October 28 to November 1 due to a planned power outage. • Facility was secured from November 22 to the end of the reporting period for freeze protection.
	830-SRC GWTS	Yes	Yes	• Facility remained secured from January 1 to April 6 for freeze protection. • Facility was secured from April 8 to April 20 due to extraction well equipment issues. • Facility was secured from June 17 to June 21 due to control system issues. • Facility was secured from June 22 to June 28 due to SVTS system testing. • Facility was secured from August 12 to August 19 to troubleshoot a control system issue. • Facility was secured from November 9 to the end of the reporting period for freeze protection.
	830-SRC SVTS	Yes	Yes	• Facility remained secured from January 1 to April 6 for freeze protection. • Facility was secured from April 8 to April 20 due to extraction well equipment issues. • Facility was secured from June 17 to June 21 due to control system issues.

Table 2.5. 2021 annual summary of treatment facility operations.

OU	Treatment facility	Operated?	In compliance?	Facility highlights
				• Facility shut down from June 24 to June 28 due to control system issues. • Facility was secured from August 12 to August 19 due to control system issues. • Facility was secured from November 9 to the end of the reporting period for freeze protection.
	830-DISS GWTS	Yes	Yes	• Facility remained secured from January 1 to June 16 for freeze protection and due to repairs at the associated CGSA GWTS. • Facility was secured or shut down in tandem with the associated CGSA GWTS. • Facility was secured from November 16 to the end of the reporting period for freeze protection.

Notes:

- = Not applicable
CGSA = Central General Services Area
CGSA-N = Central General Services Area North
DIS = Distal
DISS = Distal south
DSB = Distal site boundary
EGSA = Eastern General Services Area
GWTS = Groundwater treatment system
PRX = Proximal
PRXN = Proximal North
SRC = Source
SVTS = Soil vapor treatment system
VOC = Volatile organic compound
g = Grams
kg = Kilograms

Notes:
CGSA = Central General Services Area
CGSA-N = Central General Services Area North
DIS = Distal
DISS = Distal south
DSB = Distal site boundary
GWES = Groundwater Extraction System
GWTS = Groundwater Treatment System
mg/L = Milligrams per liter
NM = Not measured
OU = Operable unit
pH = A measure of the acidity or alkalinity of an aqueous solution
PRX = Proximal
SRC = Source

Intermediate GAC	830-SRC-VCF3I	VOCs	Weekly[a]
830-DISS GWTS			
Influent Port	830-DISS-I	Perchlorate	Quarterly
Effluent Port	830-DISS-E	Perchlorate	Monthly
		pH	Monthly

[a] Weekly monitoring for VOCs will consist of the use of a flame-ionization detector, photo-ionization detector, or other District-approved VOC detection device.

[b] Effluent monitoring no longer required due to extracted water being treated at CGSA GWTS.

[c] Effluent monitoring no longer required due to extracted water being treated at 815-SRC GWTS.

[d] Effluent monitoring no longer required due to extracted water being treated at 854-SRC GWTS.

[e] Although tritium is not treated/removed by the PIT7-SRC GWTS, tritium activities will be monitored to determine levels that are being discharged to the infiltration trench

Notes:

One duplicate and one blank (given fictitious labels) shall be taken for every 12 samples.

See Acronyms and Abbreviations in the text section of this report.

Land Use Controls for Remedial Actions at Site 300

Appendix E
Land Use Controls for Remedial Actions at Site 300

This appendix presents descriptions of the current OU-specific land use controls (LUCs) for the CERCLA remedial actions at Site 300. Based on review of any changes in environmental and operational conditions at Site 300 and risk reevaluations, these LUCs will be updated annually in the CMR reports.

This appendix includes:

- Required land use controls, including institutional controls (Table E-1);
- Maps showing the locations of the OUs and the current LUCs for each OU and subareas of OU 8 (Figures E-1 through E-13); and
- The 2021 institutional control checklist.

During 2021, there were no changes to the LUCs or maintenance procedures described in Sections 2 and 3, respectively, of the Land Use Control Implementation Plan (LUCIP) (DOE, 2019). A revised LUCIP is being prepared and will be submitted to the regulatory agencies for review in 2022.

DOE continued to conform to all land use restrictions and LUCs in 2021 and no deficiencies or inconsistencies were noted. Risk reevaluations at Site 300 are ongoing and are summarized in Section 4.1 of this CMR.

Table E-1 Land use controls for Site 300 operable units.

Operable Unit (OU)	Land use control
Sitewide	Prohibit transfer of lands with unmitigated contamination that could cause potential harm under residential or unrestricted use.
General Services Area (OU1)	Control excavation activities to prevent on-site worker exposure to contaminated subsurface soil in the vicinity of the Building 875 Dry Well Pad until it can be verified that concentrations do not pose an exposure risk to workers. Prevent water-supply use or consumption of contaminated groundwater until groundwater cleanup standards are met. The locations of land use controls for OU1 are shown on Figure E-2.
Building 834 (OU2)	Control excavation activities to prevent on-site worker exposure to contaminated subsurface soil in the Building 834 Core Area until it can be verified that concentrations do not pose an exposure risk to workers. Prevent water-supply use or consumption of contaminated groundwater until groundwater cleanup standards are met. The locations of land use controls for OU2 are shown on Figure E-3.
Pit 6 Landfill (OU3)	Maintain access restrictions to prevent inadvertent exposure of on-site workers to the landfill waste as long as the waste remains in place. Maintain the integrity of the landfill cover as long as waste remains in place. Control construction and other ground-breaking activities on the landfill to prevent cap/cover damage and/or inadvertent exposure to waste as long as the waste remains in place. Maintain access restrictions to prevent inadvertent exposure of unauthorized trespassers to landfill waste as long as the waste remains in place. Maintain land use restrictions in the vicinity of Spring 7 until annual risk reevaluation indicates that the excess cancer risk is below 10^{-6}. Prevent water-supply use or consumption of contaminated groundwater until groundwater cleanup standards are met. The locations for land use controls in OU3 are shown on Figure E-4.
High Explosives Process Area (OU4)	Control excavation activities to prevent on-site worker exposure to contaminated subsurface soil until it can be verified that concentrations do not pose an exposure risk to workers. VOCs, HMX, and RDX are present at depth in subsurface soil. Locations include: • Building 829 Open Burn Pit; • Building 807A Lagoon;

Table E-1 Land use controls for Site 300 operable units.

Operable Unit (OU)	Land use control
High Explosives Process Area (OU4) (continued)	• Building 828 Lagoon; • Building 827E Lagoon; • Building 827C/D Lagoon; • Building 807 B Lagoon; • Building 806/807 Lagoon; • Building 810 Dry Well; • Building 814 Lagoon; and • Building 815 Hard Stand and Drum Rack. Prevent water-supply use or consumption of contaminated groundwater until groundwater cleanup standards are met. Maintain land use restrictions in the vicinity of Spring 5 until annual risk reevaluation indicates that the excess cancer risk is below 10^{-6}. The locations of land use controls for OU4 are shown on Figure E-5.
Building 850 Firing Table/Pit 7 Complex (OU5); Building 850 Subarea (OU5)	Control excavation activities to prevent on-site worker exposure to contaminated subsurface soil at Building 850 until it can be verified that concentrations do not pose an exposure risk to workers. Maintain access restrictions to prevent inadvertent exposure of on-site workers to solidified soil in the CAMU as long as the waste remains in place. Maintain the integrity of the solidified soil in the CAMU as long as it remains in place. Control construction and other ground-breaking activities at the CAMU to prevent damage and/or inadvertent exposure to contaminated soil as long as it remains in place. Maintain access restrictions to prevent inadvertent exposure of unauthorized trespassers to solidified soil in the CAMU as long as the waste remains in place. Maintain land use restrictions in the vicinity of the Well 8 Spring until annual risk reevaluation indicates that the excess cancer risk is below 10^{-6}. Prevent water-supply use or consumption of contaminated groundwater until groundwater cleanup standards are met. The locations of land use controls for the Building 850 Subarea are shown on Figure E-6.

Table E-1 Land use controls for Site 300 operable units.

Operable Unit (OU)	Land use control
Pit 7 Complex Subarea (OU5)	Maintain access restrictions to prevent inadvertent exposure of on-site workers to the landfill waste as long as the waste remains in place. Maintain the integrity of the landfill cap and covers as long as waste remains in place. Control construction and other ground-breaking activities on the landfills to prevent cap/cover damage and/or inadvertent exposure to waste as long as the waste remains in place. Maintain access restrictions to prevent inadvertent exposure of unauthorized trespassers to landfill waste as long as the waste remains in place. Prevent water-supply use or consumption of contaminated groundwater until groundwater cleanup standards are met. The locations of land use controls for the Pit 7 Complex Subarea are shown on Figure E-6.
Building 854 (OU6)	Control excavation activities to prevent on-site worker exposure to contaminated subsurface soil in the Building 854 core area until it can be verified that concentrations do not pose an exposure risk to workers. Prevent water-supply use or consumption of contaminated groundwater until groundwater cleanup standards are met. The locations of land use controls for OU6 are shown on Figure E-7.
Building 832 Canyon (OU7)	Control excavation activities to prevent on-site worker exposure to contaminated subsurface soil at the Building 830 Area and the Building 832 Core Area until it can be verified that concentrations do not pose an exposure risk to workers. Maintain administrative controls to prevent on-site indoor worker inhalation exposure to volatile contaminants inside Building 830 until annual risk reevaluation indicates that the excess cancer risk is less than 10^{-6}. Building 830 is currently unoccupied. Prevent water-supply use or consumption of contaminated groundwater until groundwater cleanup standards are met. Maintain land use restrictions in the vicinity of Spring 3 until annual risk reevaluation indicates that the excess cancer risk is below 10^{-6}. The locations of land use controls for OU7 are shown on Figure E-8.

Table E-1 Land use controls for Site 300 operable units.

Operable Unit (OU)	Land use control
Building 801/Pit 8 Landfill Subarea (OU 8)	Control excavation activities to prevent on-site worker exposure to contaminated subsurface soil at the Building 801D Dry Well and Building 801 Firing Table until it can be verified that concentrations do not pose an exposure risk to workers. Maintain access restrictions to prevent inadvertent exposure of on-site workers to the landfill waste as long as the waste remains in place. Maintain the integrity of the landfill cover as long as waste remains in place. Control construction and other ground-breaking activities on the landfill to prevent cap/cover damage and/or inadvertent exposure to waste as long as the waste remains in place. Maintain access restrictions to prevent inadvertent exposure of unauthorized trespassers to landfill waste as long as the waste remains in place. Prevent water-supply use or consumption of contaminated groundwater until groundwater cleanup standards are met. The locations of land use controls for The Building 801/Pit 8 Landfill area are shown on Figure E-9.
Building 833 Subarea (OU8)	Maintain engineering and administrative controls to prevent on-site indoor worker inhalation exposure to volatile contaminants inside Building 833 until annual risk reevaluation indicates that the excess cancer risk is less than 10^{-6}. Control excavation activities to prevent on-site worker exposure to contaminated subsurface soil in the Building 833 Core Area until it can be verified that concentrations do not pose an exposure risk to workers. Prevent water-supply use or consumption of contaminated groundwater until groundwater cleanup standards are met. The locations of land use controls for the Building 833 Subarea are shown on Figure E-10.
Building 845 Firing Table/Pit 9 Landfill Subarea (OU8)	Control excavation activities to prevent on-site worker exposure to contaminated subsurface soil at the Building 845 Firing Table until it can be verified that concentrations do not pose an exposure risk to workers. Maintain access restrictions to prevent inadvertent exposure of on-site workers to the landfill waste as long as the waste remains in place. Maintain the integrity of the landfill cover as long as waste remains in place.

Table E-1 Land use controls for Site 300 operable units.

Operable Unit (OU)	Land use control
Building 845 Firing Table/Pit 9 Landfill Subarea (OU8) (continued)	Control construction and other ground-breaking activities on the landfill to prevent cap/cover damage and/or inadvertent exposure to waste as long as the waste remains in place. Maintain access restrictions to prevent inadvertent exposure of unauthorized trespassers to landfill waste as long as the waste remains in place. The locations of land use controls for the Building 845 Firing Table/Pit 9 Landfill Subarea are shown on Figure E-11.
Building 851 Firing Table Subarea (OU8)	Control excavation activities to prevent on-site worker exposure to contaminated surface and subsurface soil throughout the Building 851 area until it can be verified that concentrations do not pose an exposure risk to workers. Maintain land use restrictions in the vicinity of contaminated surface soil at Building 851 until the protectiveness of the current remedy can be confirmed. The locations of land use controls for the Building 851 Firing Table Subarea are shown on Figure E-12.
Pit 2 Landfill Subarea (OU8)	Maintain access restrictions to prevent inadvertent exposure of on-site workers to the landfill waste as long as the waste remains in place. Maintain access restrictions to prevent inadvertent exposure of unauthorized trespassers to landfill waste as long as the waste remains in place. Maintain the integrity of the landfill cover as long as waste remains in place. Control construction and other ground-breaking activities on the landfill to prevent cover damage and/or inadvertent exposure to waste as long as the waste remains in place. Prevent water-supply use or consumption of contaminated groundwater until groundwater cleanup standards are met. The locations of land use controls for the Pit 2 Landfill Subarea are shown on Figure E-13.

Institutional Controls Monitoring Checklist

This checklist will be used to conduct monitoring of institutional and engineered controls that are used to prevent exposure to contamination. The checklist will be completed at least annually and the results will be reported in the annual Compliance Monitoring Reports.

Institutional Control	Status[a]	Explanation/Observation of Corrective Action
Verify that the occupancy warning signs are visible at Building 834D.	N/A	Institution control no longer required as documented in the *Addendum to the Fourth Five-Year Review for the Building 834 Operable Unit at Lawrence Livermore National LaboratorySite 300 March 2021*
Verify that the Pit 6 Landfill was inspected within the last year and deficiencies were corrected.[b]	Yes	Inspected on 3/29/21. All deficiencies corrected.
Verify that signage is in place at the Pit 6 Landfill prohibiting unauthorized access and excavation.	Yes	Inspected 3/29/21. Signs are in place and visible.
Verify that the fences and warning signs at the site boundary and control entry are in proper condition.[c]	Yes	Fencing and warning signs at the site entrance and along Coral Hollow Rd are in proper condition. An inspections process and plan has been developed and implementation began in 2021. However, about 75% of the entire perimeter fence and associated warning signs were inspected in 2021. The remaining 25% of perimeter fencing will be inspected in 2022. Any needed repairs to the barbed wire fencing or missing signage were addressed.
Verify that the Building 850 Soil Solidification Corrective Action Management Unit (CAMU) was inspected within the last year and deficiencies were corrected.[d]	Yes	Inspected on 6/14/2021. Maintenance performed as needed.
Verify that the Pit 7 Complex Drainage Diversion System was inspected within the last year and deficiencies were corrected.[e]	Yes	Inspections performed monthly during the rainy season of 2021. All deficiencies corrected.
Verify that the Pit 7 Complex landfills were inspected within the last year and deficiencies were corrected.[b]	Yes	Inspected on 4/14/21. All deficiencies corrected.
Verify that signage is in place at the Pit 7 Complex Landfills prohibiting unauthorized access and excavation.	Yes	Inspected on 4/14/21. Signs are in place.
Verify that the occupancy warning signs are visible at Building 854A.	N/A	Institution control no longer required as documented in the *Addendum to the Five-Year Review for East/West Firing Areas at Lawrence Livermore National Laboratory Site 300 March 2021*
Verify that the occupancy warning signs are visible at Building 830.	Yes	Inspected on 12/21/21. Sign in place on two doors. The building is currently not occupied.

Institutional Control	Status[a]	Explanation/Observation of Corrective Action
Verify that the occupancy warning signs are visible at Building 833.	Yes	Inspected on 12/21/21. The building is currently not occupied.
Check that the engineered controls (heating, ventilating, and air-conditioning system [HVAC]) for Building 833 are functioning properly.	No	Engineering controls in the form of HVAC are no longer applicable. A sub-slab de-pressurization system (SSDS) was continuously operated during 2021.
Check that the engineered controls (SSDS) for Building 833 are functioning properly.	Yes	The SSDS has been functioning properly.
Verify that the Pit 2 Landfill was inspected within the last year and deficiencies were corrected.[b]	Yes	Inspected on 1/25/21, 4/7/21, 7/13/21, and 10/18/21. All deficiencies corrected.
Verify that the Pit 8 Landfill was inspected within the last year and deficiencies were corrected.[b]	Yes	Inspected on 1/25/21, 4/7/21, 7/13/21, and 10/18/21. All deficiencies corrected.
Verify that the Pit 9 Landfill was inspected within the last year and deficiencies were corrected.[b]	Yes	Inspected on 1/25/21, 4/7/21, 7/13/21, and 10/18/21. All deficiencies corrected.

Notes:

[a] Satisfactory status indicated by "Yes". Unsatisfactory status indicated by "No". Unsatisfactory status requires explanation. The Inspector shall immediately notify the Environmental Restoration Department of any unsatisfactory status.

[b] The landfills are inspected and maintained by LLNL Maintenance and Utility Services. Inspections are documented and the results are provided to the Environmental Restoration Department and reported in the annual Compliance Monitoring Reports.

[c] Perimeter fences are inspected by LLNL Security annually.

[d] The Building 850 CAMU is inspected and maintained by LLNL Maintenance and Utility Services. Inspections are documented and the results are provided to the Environmental Restoration Department and reported in the annual Compliance Monitoring Reports.

[e] The Pit 7 Drainage Diversion System is inspected and maintained by LLNL Maintenance and Utility Services. Inspections are documented and the results are provided to the Environmental Restoration Department and reported in the annual Compliance Monitoring Reports.

Appendix F-1

Vapor Intrusion
Building Prioritization

Appendix F-1. Vapor Intrusion Building Prioritization

This appendix contains the annual update to the building priority list for the Lawrence Livermore National Laboratory (LLNL) Site 300.

The building prioritization uses the most recent groundwater screening levels and highest concentration in groundwater within 100 feet of a building footprint. The highest concentration in groundwater was determined by selecting the higher value of either the measured concentration in a nearby well (data range January 1, 2017, through December 31, 2021) or the plume concentration (based on the total volatile organic compound groundwater plumes presented in the Annual 2016 Compliance Monitoring Report for Site 300).

The following tables and figures detail the approach used in prioritizing and ranking buildings at Site 300 based on the potential for vapor intrusion from subsurface contamination to indoor air.

Appendix F-1 Table 1. List of buildings and associated well(s) in the first water-bearing zone within 100 feet of the building footprint.

The maximum concentration for each contaminant of concern (COC) that exceeded the groundwater screening value is presented for each well (data range January 1, 2017, through December 31, 2021). The maximum concentration for each COC for each building is also presented on the same row as the building number. If there is no concentration data presented for a well, the well was not sampled during the data review period. If there is no concentration data presented for a building, there are no wells in the first water-bearing zone within 100 feet of the building footprint. If the value is zero, the concentration of the contaminant is below the detection limit.

All COCs that are known to have any measured concentrations above the Environmental Protection Agency (EPA) Vapor Intrusion Screening Level (VISL) or California Department of Toxic Substances and Control (CA DTSC) screening values in samples collected from wells completed in the first water-bearing zone were included in the analysis.

Appendix F-1 Table 2. List of buildings and the maximum concentration for each contaminant of concern that exceeded the groundwater screening value observed in a well in the first water-bearing zone within 100 feet of the building footprint.

Maximum concentrations in this table are obtained from the detailed concentration data presented in Appendix F-1 Table 1. If there is no concentration data presented for a building, there are no wells in the first water-bearing zone within 100 feet of the building footprint (data range January 1, 2017, through December 31, 2021). If the value is zero, the concentration of the contaminant is below the detection limit.

Appendix F-1 Table 3. List of buildings and the maximum concentration of total volatile organic compounds in the first water-bearing zone within 100 feet of the building footprint.

If there is no concentration data presented for a building, there is no plume in the first water-bearing zone within 100 feet of the building footprint (plume data is based on the total volatile organic compound groundwater plumes presented in the Annual 2016 Compliance Monitoring Report for Site 300).

Appendix F-1. Vapor Intrusion Building Prioritization

Appendix I-1 Table 4. List of buildings and the maximum concentration for each contaminant of concern that exceeded the groundwater screening value observed in a well or total volatile organic compound plume (assumed to be all trichloroethene) in the first water-bearing zone within 100 feet of the building footprint. Maximum concentrations in this table are obtained by including the highest concentrations from Appendix F-1 Tables 2 and 3. If there is no concentration data presented for a building, there is no well or total volatile organic compound plume in the first water-bearing zone within 100 feet of the building footprint. Total volatile organic compound plumes (assumed to be all trichloroethene (TCE)) were used for the plume analysis as it is not possible to generate individual volatile organic compound plumes, other than TCE, due to their sporadic distribution.
Appendix F-1 Table 5. Site-specific groundwater screening levels for Lawrence Livermore National Laboratory. The groundwater screening levels were determined using site-specific parameters. Target Cancer Risk = 1E-06 or Target Hazard Quotient = 1.0 Groundwater temperature = 20 degrees Celsius Industrial site use
Appendix F-1 Table 6. Prioritized list of buildings, maximum concentration for each contaminant of concern divided by its respective screening level, final rank score, and rank group for buildings. The sum of the individual unitless scores is used to determine a final rank for each building. A plot of the final rank for each building (Appendix F-1 Figure 1) was used to determine the rank groups based on changes in slope. Final Rank Score = Conc(TCE) / SL(TCE) + Conc(PCE) / SL(PCE) + … + Conc(CTET) / SL(CTET) Where; Conc = source concentration in groundwater from Appendix F-1 Table 4, SL = Screening level from Appendix F-1 Table 5, TCE = Trichloroethene, PCE = Tetrachloroethene, CTET = Carbon tetrachloride. All volatile chemicals exceeding screening levels were used in ranking.
Appendix F-1 Figure 1. Distribution of the final rank score for all buildings. The change in slope in the distribution of the final rank score is used to determine the four rank groups.

Appendix F-1 Table 1. List of buildings and associated well(s) in the first water-bearing zone within 100 feet of the building footprint.

Appendix F-1 Table 5. Site specific groundwater screening levels for Lawrence Livermore National Laboratory.

Constituent	CAS#	Groundwater Screening Level µg/L
Target groundwater concentration at TCR = 1E-06 or THQ = 1.0, Groundwater temperature = 20 degC, Industrial site use		
1,1,1-Trichloroethane[1]	71-55-6	7700
1,1,2-Trichloroethane	79-00-5	29
1,1-Dichloroethane	75-34-3	41
1,1-Dichloroethene[1]	75-35-4	340
1,2-Dichloroethane	107-06-2	12
Carbon tetrachloride	56-23-5	2.2
Chloroform	67-66-3	4.3
Tetrachloroethene[1]	127-18-4	3.6
Trichloroethene	79-01-6	9.3
Trichlorofluoromethane[1]	75-69-4	1600
Trichlorotrifluoroethane	76-13-1	1200
Vinyl chloride[1]	75-01-4	0.16
cis-1,2-Dichloroethene[1]	156-59-2	260
trans-1,2-Dichloroethene	156-60-5	550

Reference:

The site-specific screening values were determined using U.S. Environmental Protection Agency (https://epa-visl.ornl.gov/cgi-bin/visl_search), Vapor Intrusion Screening Level (VISL) Calculator (accessed February 24, 2022) in conjunction with the toxicity values (reference concentration and cancer risk values) to meet the requirements outlined in the Human Health Risk Assessment Note 10 – DTSC Modified Toxicity Criteria (February 2019).

Notes:

[1]DTSC toxicity values were selected and used in the VISL Calculator.

TCR = Target cancer risk

THQ = Target hazard quotient

THQ = Target hazard quotient

CAS# = Chemical Abstracts Service Registry Number

µg/L = Micrograms per liter

Appendix F-1 Table 6. Prioritized list of buildings, maximum concentration for each contaminant of concern divided by its respective screening level, final rank score, and rank group for buildings.

Appendix F-4

Soil Vapor Extraction and Vapor Intrusion Mitigation System Zone of Influence

1. Introduction

In the Addenda to Five-Year Reviews (FYR) for the Lawrence Livermore National Laboratory (LLNL), Site 300 (Demir et al. 2021a, 2021b, 2021c, and 2021d), the Remedial Project Managers (RPMs) agreed to a recommendation to develop a contingency plan for indoor air sampling when soil vapor extraction (SVE) or vapor intrusion (VI) mitigation systems are off-line for an extended period. As part of this recommendation, the Department of Energy (DOE)/LLNL agreed to implement a contingency plan using the following criteria:

- DOE/LLNL will develop a list of buildings in the vicinity of each SVE and VI mitigation system.
- If an SVE or VI mitigation system is off-line for more than 30 days, DOE/LLNL will deploy Radiello 130® passive diffusive samplers in nearby buildings.

This document describes the approach used to develop the list of buildings in the zone of influence of SVE and VI mitigation system wellfields at LLNL Site 300, for the following Operable Units (OUs):

- OU 1: General Services Area
- OU 2: Building 834
- OU 6: Building 854
- OU 7: Building 832 Canyon
- OU 8: Building 833

2. Soil vapor extraction and vapor intrusion mitigation zone of influence

There are currently five operational SVE systems and one operational VI mitigation system at LLNL Site 300. They are located in areas where residual unsaturated zone contamination remains. The selected remedy for unsaturated zone cleanup at Site 300 is soil vapor extraction (DOE, 2008). Soil vapor extraction at Site 300 began in the 1990s at one location and by the early 2000s all five SVE systems were operational. The VI mitigation system began operation in 2019. The SVE and VI mitigation systems discussed in this document are:

- Central General Services Area Soil Vapor Treatment System (CGSA SVTS)
- Building 834 Soil Vapor Treatment System (834 SVTS)
- Building 832 Source Soil Vapor Treatment System (832-SRC SVTS)
- Building 830 Source Soil Vapor Treatment System (830-SRC SVTS)
- Building 854 Source Soil Vapor Treatment System (854-SRC SVTS)
- Building 833 Sub-slab Depressurization System (833-SSDS)

DOE/LLNL applied a two hundred foot radius around SVE and VI mitigation system extraction wells to delineate the zone of influence in the subsurface. The zone of influence of each extraction well is related with the extraction flow rate, relative air permeability near each well, and subsurface heterogeneity. DOE/LLNL has conducted pneumatic testing in the past and is aware that the zone of influence of each well varies by location. The average zone of influence of extraction wells is conservatively estimated to be two hundred feet based on pneumatic tests and long-term concentration changes in nearby monitor wells. DOE/LLNL will continue to conduct pneumatic testing to better

define the zone of influence for each extraction well. The current zone of influence selected for this analysis is conservatively large to ensure that potential vapor intrusion from subsurface contamination to indoor air would be evaluated in nearby buildings when SVE or VI mitigation systems are off-line for an extended period. The estimated zone of influence for each SVE or VI mitigation system is shown on Appendix F-4 Figures 1 through 6.

Appendix F-4 Table 1 contains the list the buildings where indoor air sampling will be conducted using Radiello 130® passive diffusive samplers if an SVE or VI mitigation system is off-line for more than 30 days. These sampling events are independent from the long-term indoor air sampling program, however, the results from sampling events will be incorporated into the long-term program as they will represent the worst-case conditions. The list of buildings will be updated annually as DOE/LLNL continues to conduct pneumatic tests to refine the zone of influence for each extraction well.

Appendix G Table 1. Measurement Quality Objectives for Analytical Data.
Appendix G Table 2. Measurement Quality Objective Results for 2020 Analytical Data.

2021 Analytical Data Quality Assurance Summary

1. Introduction

During 2021, the Lawrence Livermore National Laboratory (LLNL) Livermore Site and Site 300 environmental restoration programs collected water, soil, and vapor samples for analytical laboratory analysis. The Quality Assurance Project Plan (QAPP) (LLNL, 2020) established measurement quality objectives (MQOs) for the analytical data obtained from analysis of environmental samples (Appendix G Table 1). The purpose of the Quality Assurance Summary (QAS) is to determine if the analytical data MQOs, based upon the PARCCS (precision, accuracy, representativeness, comparability, completeness, and sensitivity) parameters have been met. Also provided in this QAS are summaries of analytical laboratory certifications, assessments, and performance testing as well as internal assessments conducted during 2021.

2. Analytical Data Issues – Rejected and Suspect Data

Data are most commonly rejected and assigned "R" qualifiers when the presence or absence of the analyte(s) of interest cannot be verified, most often due to failure to meet quality control (QC) criteria. Data are qualified as suspect and assigned "S" qualifiers when the results, based upon sample type, location, or previous result history are anomalous and are believed to have been switched or incorrectly identified during the sample collection, preparation, or analysis process. With the exception of three samples, most data rejected during 2021 consisted of single VOC analytes, mostly bromomethane and 2-chloroethylvinylether, known to be problematic and with no detection histories at LLNL. No data were qualified as suspect during 2021.

- Volatile organic compound (VOC) results from a sample collected from Livermore Site monitor well W-506 during March were rejected and assigned "R" data qualifiers due to a laboratory error that raised reporting limits to unacceptable levels. A new sample was collected and acceptable results were obtained for this location.
- VOC results from a sample collected from Site 300 monitor well W-854-3308 during March were rejected and assigned "R" data qualifiers due to poor QC results (very low matrix spike [MS] and matrix spike duplicate [MSD] recoveries). This was a duplicate sample collected for inter-laboratory comparison. The routine sample provided acceptable results for this location.
- VOC results from the 127 feet (ft) sample collected from Livermore Site borehole B-3702 during July were rejected and assigned "R" data qualifiers due to poor QC results (low internal standards results). Resampling was not possible, but acceptable VOC data from other depths in this borehole were obtained.

An additional data issue that occurred during 2021 was the need to assign "H" qualifiers to results from 29 perchlorate samples that were analyzed outside of their hold times due to instrument failures and errors by a subcontracted laboratory. LLNL authorized analysis out-of-hold because the samples had been collected late in the quarter and there was insufficient time and resources for resampling.

3. Analytical Accuracy and Precision

3.1. Analytical Accuracy

Accuracy, a quantitative parameter, indicates how close a measurement is to the actual value. LCS recovery, expressed as a percentage, is used as an indicator of analytical accuracy. An LCS is prepared by spiking a clean matrix, usually blank (de-ionized) water, with known concentrations of the target analytes. It is then prepared and analyzed like a regular sample. Recovery of the spiked analytes must fall within a certain percentage range, known as the control limits, for the results to be acceptable. The LCS analytical control limits used by analytical laboratories can be obtained from the method paper, the TNI Standard (2016), the DoD/DOE Quality System Manual (QSM) (2019), or from the laboratory's own recovery data, but must be approved by LLNL. The analytical control limits vary somewhat between laboratories and results received that fall outside the laboratories stated control limits are rejected. However, to meet the LLNL MQO for accuracy 85% or more of the LCS recoveries, each analyte group must fall within the tighter control limit ranges specified in Appendix G Table 1.

LCS recovery charts and brief summaries of the LCS recovery results for volatile organic compounds (VOCs), HE compounds, metals, radionuclides (tritium and uranium-238), and anions (nitrate and perchlorate), the five analytical groups with QAPP-established MQOs, are provided below for aqueous, soil, and air sample analyses. Note that the analytical laboratories will not be identified by name in the charts or summaries presented in this document. Data sources will be identified by letter only in the charts and text.

3.1.1. LCS Percent Recovery Results for 2021 Aqueous Analyses

3.1.1.1. Volatile Organic Compounds

Figure G-1 provides LCS percent recovery results for VOCs. The MQO established for VOCs is for at least 85% of the LCS recoveries to be within the 80–120% range.

- QC sample results from EPA Methods 624.1, 8260, and RSK-175.
- 95% of LCS recoveries within 80–120% MQO range. Individually, each laboratory also met the MQO.
- Results outside MQO: 618 (5%), mostly for problematic analytes such as bromomethane, chloroethane, chloromethane, and 2-chloroethylvinylether.

The MQO for accuracy was met for VOC analyses.

3.1.1.2. High-Explosive Compounds

Figure G-2 provides LCS percent recovery results for HE compounds. The MQO established for HE compounds is for at least 85% of the LCS recoveries to be within the 80–120% range.

- QC sample results from EPA Method 8330.
- 98% of LCS recoveries within the 80–120% MQO range.
- Results outside MQO: 23, including 2 HMX and 2 RDX.

The MQO for accuracy was met for HE Compound analyses.

3.1.1.3. Metals

Figure G-3 provides LCS percent recovery results for metals. The MQO established for metals is for at least 85% of the LCS recoveries to be within the 90–110% range.

- QC sample results from EPA Methods 200.7, 200.8, 218.6, 245.1, 6010, 6020, and 7470.
- 96% of LCS recoveries within the 90–110% MQO range.
- Results outside MQO: 103, distributed among the analytes.

Overall, the results for metals analyses met the MQO for accuracy, but individually, laboratory D, at 78%, did not meet the 85% MQO.

3.1.1.4. Radionuclides

3.1.1.4.1. Tritium

Figure G-4 provides LCS percent recovery results for tritium. The MQO established for tritium is for at least 85% of the LCS recoveries to be within the 80–120% range.

- QC sample results from liquid scintillation spectrometry.
- 98% of LCS recoveries within the 80–120% MQO range
- Results outside MQO: 2 results below the MQO.

The MQO for accuracy was met for tritium analyses.

3.1.1.4.2. Uranium-238

Figure G-5 provides LCS percent recovery results for uranium-238. The MQO established for uranium-238 is for at least 85% of the LCS recoveries to be within the 85–115% range.

- QC sample results from alpha spectrometry.
- 100% of LCS recoveries within the 85–115% MQO range
- Results outside MQO: none.

The MQO for accuracy was met for uranium-238 analyses.

3.1.1.5. Anions

3.1.1.5.1. Nitrate

Figure G-6 provides LCS percent recovery results for nitrate. The MQO established for nitrate requires that 100% of LCS recoveries must be within the 90–110% range.

- QC sample results from EPA Method 300.0.
- 100% of LCS recoveries within the 90–110% MQO range
- Results outside MQO: none.

The MQO for accuracy was met for nitrate analyses.

3.1.1.5.2. Perchlorate

Figure G-7 provides LCS percent recovery results for perchlorate. The MQO established for perchlorate requires that 100% of LCS recoveries must be within the 85–115% range.

- QC sample results from EPA Method 314.0.
- 100% of LCS recoveries within 85–115% MQO range

- Results outside MQO: none.

The MQO for accuracy was met for perchlorate analyses.

3.1.2. LCS Recovery Results for 2021 Soil Samples

Volatile Organic Compounds

Figure G-8 provides LCS percent recovery results for soil samples collected as part of the direct-push sampling survey in the Livermore Site TFD Helipad and East Traffic Circle North areas and other soil samples collected during drilling operations at Livermore Site for VOC analysis. The MQO established for VOCs is for at least 85% of the LCS recoveries to be within the range of 80–120%.

- QC sample results from EPA Method 8260.
- 98% of LCS recoveries within 80–120% MQO range
- Results outside MQO: 11, mostly bromomethane, chloromethane, and vinyl chloride which are known to be problematic.

The MQO for accuracy was met for soil sample VOC analyses.

3.1.3. LCS Recovery Results for 2021 Air Samples

Volatile Organic Compounds

Figure G-9 provides LCS percent recovery results for indoor air samples collected for vapor intrusion monitoring, soil vapor samples collected during the direct-push sampling survey in the Livermore Site TFD Helipad and East Traffic Circle North areas and routine soil vapor samples collected at Livermore Site and Site 300 for VOC analysis. The MQO established for VOCs is for at least 85% of the LCS recoveries to be within the range of 80–120%.

- QC sample results from EPA Method TO-17 and EPA Method TO-15 for indoor air and soil vapor, respectively.
- 96% of LCS recoveries within 80–120% MQO range. Individually, the recoveries for each method, TO-15 and TO-17, also met the MQO.
- Results outside MQO: 22 TO-17 results and 105 TO-15 results, distributed among the analytes.

The MQO for accuracy was met for air sample VOC analyses.

3.2. Analytical Precision

Precision, a quantitative parameter, is the degree of agreement between measurements of the same property under the same conditions. The indicator for precision is the relative percent difference (RPD) calculated between pairs of samples using the following equation:

$$RPD = \frac{|R_1 - R_2|}{\left(\frac{R_1 + R_2}{2}\right)} \times 100$$

Where R_1 is the routine sample analytical result and R_2 is the duplicate sample analytical result. Analytical precision is often determined using RPDs calculated from MS and MSD pairs. A matrix spike is prepared by spiking an actual sample matrix, rather than the clean matrix used for an LCS, with known concentrations of the target analytes. RPD may also be calculated using LCS and LCSD pairs, or sample and sample duplicate pairs. Most of the LLNL water and soil sample pair comparisons

for organic and inorganic analyses use MS and MSD results, air samples use LCS and LCSD results, and radionuclide analyses compare sample and sample duplicate results. It should also be noted that RPD is often not a useful indicator of precision for soil sample analyses as it may indicate more about sample heterogeneity than analytical precision.

Application of the RPD calculation is not always possible or appropriate. The following guidelines are used to determine when to apply the RPD calculation and how to compare duplicate pair results for acceptability when the RPD calculation is not applicable:

1. The standard RPD calculation is used when one or both results are greater than 5x the reporting limit.
2. When both results are less than 5x the reporting limit, results are acceptable when the difference between the results is less than or equal to the reporting limit.
3. When both results are less than the reporting limit, and the reporting limits are the same, the results are acceptable.
4. When both results are less than the reporting limit, but the reporting limits are different, the difference between ½ the reporting limits must be less than or equal to the smaller reporting limit to be acceptable.
5. When one result is a detection greater than the reporting limit, and the other result is less than the reporting limit (the reporting limits may be different), the difference between the detection and ½ the reporting limit must be less than or equal to the smaller reporting limit to be acceptable.
6. For purposes of plotting the results of duplicate pair comparisons when the RPD calculation is not used, acceptable results will be assigned a default value of "0" and unacceptable results will be assigned a default value of "50", which is noticeably greater than any of the MQO RPDs.

QC sample pair comparisons for VOCs, HE compounds, metals, radionuclides (tritium and uranium-238), and anions (nitrate and perchlorate), the five analytical groups with QAPP-established MQOs, are discussed below for aqueous, soil, and air sample matrices. Note that the analytical laboratories are not identified by name in the charts or summaries presented in this document. Data sources are identified by letter only in the charts and text.

3.2.1. Relative Percent Duplicate Results for 2021 Aqueous Analyses

3.2.1.1. Volatile Organic Compounds

Figure G-10 provides MS/MSD relative percent difference results for VOCs. The MQO established for VOCs requires that at least 85% of RPD results are acceptable or less than or equal to 15%.

- QC sample results from EPA Methods 624.1 and 8260.
- 94% of RPD results are acceptable or less than or equal to 15%.
- Results outside MQO: 802 (6%), distributed among the analytes.

The overall results for VOC analyses met the MQO for precision, but individually, laboratory D, at 76%, did not meet the 85% MQO.

3.2.1.2. High-Explosive Compounds

Figure G-11 provides MS/MSD relative percent difference results for HE compounds. The MQO established for HE compounds requires that at least 85% of RPD results are acceptable or less than or equal to 25%.

- QC sample results from EPA Method 8330.
- 99.5% of RPD results are acceptable or less than or equal to 25%.
- Results outside MQO: 5, none for HMX or RDX.

The MQO for precision was met for HE compounds analyses.

3.2.1.3. Metals

Figure G-12 provides MS/MSD relative percent difference results for metals. The MQO established for metals requires that at least 85% of RPD results are acceptable or less than or equal to 10%.

- QC sample results from EPA Methods 200.7, 200.8, 218.6, 245.1, 6010, 6020, and 7470.
- 98% of RPD results are acceptable or less than or equal to 10%.
- Results outside MQO: 44, distributed among the analytes.

The MQO for precision was met for metals analyses.

3.2.1.4. Radionuclides

3.2.1.4.1. Tritium

Figure G-13 provides QC duplicate relative percent difference results for tritium. The MQO established for tritium requires that at least 85% of RPD results are acceptable or less than or equal to 20%.

- QC sample results from liquid scintillation spectrometry.
- 100% of RPD results are acceptable or less than or equal to 20%.
- Unacceptable results: none.

The MQO for precision was met for tritium analyses.

3.2.1.4.2. Uranium-238

Figure G-14 provides QC duplicate relative percent difference results for uranium-238. The MQO established for uranium-238 requires that at least 85% of RPD results are acceptable or less than or equal to 20%.

- QC sample results from alpha spectrometry.
- 88% of RPD results are acceptable or less than or equal to 20%.
- Results outside MQO: 5, 2 from laboratory B and 3 from laboratory E.

Overall, the RPD results for uranium-238 analyses met the MQO, but individually, laboratory E, at 67%, did not meet the 85% MQO.

3.2.1.5. Anions

3.2.1.5.1. Nitrate

Figure G-15 provides MS/MSD relative percent difference results for nitrate. The MQO established for nitrate requires that at least 85% of RPD results are acceptable or less than or equal to 5%.

- QC sample results from EPA Method 300.0.
- 98% of RPD results are acceptable or less than or equal to 5%.
- Results outside MQO: 8, 1 from laboratory C with an RPD of 7.1%; 2 from laboratory A, maximum RPD 6.4; 5 from laboratory D, maximum RPD 5.7,

The MQO for precision was met for nitrate analyses.

3.2.1.5.2. Perchlorate

Figure G-16 provides MS/MSD relative percent difference results for perchlorate. The MQO established for perchlorate requires that at least 85% of RPD results are acceptable or less than or equal to 10%.

- QC sample results from EPA Method 314.0.
- 99.4% of RPD results are acceptable or less than or equal to 10%.
- Results outside MQO: 1, 1 from laboratory A with an RPD of 14%.

The MQO for precision was met for perchlorate analyses.

3.2.2. Duplicate Pair Comparison Results for 2021 Soil Samples

3.2.2.1. Volatile Organic Compounds

Figure G-17 provides MS/MSD relative percent difference results for soil samples collected for VOC analysis at the Livermore Site as part of the direct-push sampling survey in the Livermore Site TFD Helipad and East Traffic Circle North areas and from other drilling operations. The MQO established for VOCs requires that at least 85% of RPD results are acceptable or less than or equal to 15%.

- QC sample results from EPA Method 8260.
- 94% of RPD results are acceptable or less than or equal to 15%.
- Results outside MQO: 28, with the exception of 1 chloroform result, all results for LLNL target analytes met the MQO.

The MQO for precision was met for soil sample VOC analyses.

3.2.3. Duplicate Pair Comparison Results for 2021 Air Samples

3.2.3.1. Volatile Organic Compounds

Figure G-18 provides LCS/LCSD relative percent difference results for indoor air samples collected for vapor intrusion monitoring at Livermore Site and Site 300, soil vapor samples collected as part of the direct-push sampling survey in the Livermore Site TFD Helipad and East Traffic Circle North areas, and routine soil vapor samples collected at Livermore Site and Site 300 for VOC analysis. The MQO established for VOCs requires that at least 85% of RPD results are acceptable or less than or equal to 15%.

- QC sample results from EPA Method TO-17 and EPA Method TO-15 for indoor air and soil vapor, respectively.
- 99.8% of RPD results are acceptable or less than or equal to 15%.
- Results outside MQO: 8, 1 TO-15 result from laboratory A with an RPD of 16%, and 7 TO-17 results from laboratory F with a maximum RPD of 26%. Results for all LLNL target analytes were within the MQO.

The MQO for precision was met for air sample VOC analyses.

4. Field QC Precision and Completeness

During preparation of quarterly sampling plans, locations are selected for collection of collocated field QC duplicate samples following the procedure provided in SOP 4.9, *Collection of Field QC Samples*. The MQO (Appendix G Table 1) requires that 10% of all samples collected will have a collocated field duplicate with half of the duplicates (5% of the total samples) sent for inter-laboratory comparisons and the other half sent for intra-laboratory comparisons. The RPD or comparison (see Section 3.2 for RPD formula, guidelines for duplicate pair comparisons, and default values for plots) between the analytical results for the field QC sample pairs provides an indication of the precision of the entire sampling and analysis process, and inter-laboratory results provide an indication of the comparability of analytical results between laboratories. Because the entire sampling and analysis process is evaluated, the RPD limits (Appendix G Table 1) for field QC sample results comparisons are larger than those for analytical QC sample results.

Field QC sample pair comparisons for VOCs, HE compounds, metals, radionuclides (tritium and uranium-238), and anions (nitrate and perchlorate), the five analytical groups with QAPP-established MQOs, are discussed below for aqueous, soil, and air samples. Note that the analytical laboratories are not identified by name in the charts or summaries presented in this document. Data sources are identified by letter only in the charts and text.

4.1. Field QC Duplicate Pair Comparison Results for 2021 Aqueous Samples

4.1.1. Volatile Organic Compounds

Figure G-19 provides inter-laboratory and intra-laboratory duplicate pair comparison results for VOCs. The MQO established for VOCs requires that at least 85% of RPD results are acceptable or less than or equal to 25%.

- The duplicate pairs were analyzed using EPA Methods 524.2, 624.1, 602 or 8260 with concentrations ranging from less than 0.2 ug/L to 3,480 ug/L.
- 97% of the duplicate pair comparisons were acceptable or had RPDs of less than or equal to 25%
- Results outside MQO: 276, with 265 (96%) inter-laboratory comparisons, most involving 2-chloroethylvinylether results with different reporting limits from each laboratory. The maximum RPD was 177, the result of an intra-laboratory comparison of tetrachloroethene results of 50 ug/L and 3.1 ug/L.
- 9% of samples were collected in duplicate with 6% analyzed for inter-laboratory comparison and 3% analyzed for intra-laboratory comparison.

For VOC analyses, the MQOs for acceptable results and inter-laboratory comparisons were met. With 9% duplicate samples and 3% intra-laboratory comparisons, the respective MQOs of 10% and 5% were not met. Future sampling plans will require adjustments to meet the MQOs.

4.1.2. High-Explosive Compounds

Figure G-20 provides inter-laboratory and intra-laboratory duplicate pair comparison results for high explosive compounds. The MQO established for high explosive compounds requires that at least 85% of RPD results are acceptable or less than or equal to 35%.

- The duplicate pairs were analyzed using EPA Method 8330 with concentrations ranging from less than 1 ug/L to 22 ug/L.
- 100% of the duplicate pair comparisons were acceptable or had RPDs of less than or equal to 35%.
- Results outside MQO: none.
- 13% of samples were collected in duplicate with 8% analyzed for inter-laboratory comparison and 5% analyzed for intra-laboratory comparison.

For high explosive compound analyses, the MQOs for precision and duplicate sample collection have been met.

4.1.3. Metals

Figure G-21 provides inter-laboratory and intra-laboratory duplicate pair comparison results for metals. The MQO established for metals requires that at least 85% of RPD results are acceptable or less than or equal to 20%.

- The duplicate pairs were analyzed using EPA Methods 200.7, 200.8, 218.6, and 245.1 with concentrations ranging from less than 0.0001 mg/L to 790 mg/L.
- 88% of the duplicate pair comparisons were acceptable or had RPDs of less than or equal to 20%.
- Results outside MQO: 73, the maximum calculated RPD of 38 was for an intra-laboratory barium comparison; there were 61 inter-laboratory cases with both results less than the reporting limit, but due to reporting limit differences useful comparisons were not possible.
- 9.4% of samples were collected in duplicate with 4.5% analyzed for inter-laboratory comparison and 4.9% analyzed for intra-laboratory comparison.

For metals analyses, the MQO for precision was met. With 9.4% duplicate samples, 4.5% inter-laboratory comparisons, and 4.9% intra-laboratory comparisons, the respective MQOs of 10%, 5%, and 5% were nearly met. Adjustment of future sampling plans will ensure these MQOs are met .

4.1.4. Radionuclides

Inter-laboratory and intra-laboratory duplicate pair comparison results for tritium and uranium-238 are discussed below.

4.1.4.1. Tritium

Figure G-22 provides inter-laboratory and intra-laboratory duplicate pair comparison results for tritium. The MQO established for tritium requires that at least 85% of RPD results are acceptable or less than or equal to 30%.

- The duplicate pairs were analyzed using liquid scintillation spectrometry with activities ranging from less than 100 pCi/L to 27,600 pCi/L.
- 99% of the duplicate pair comparisons were acceptable or had RPDs of less than or equal to 30%.
- Results outside MQO: 1 inter-laboratory tritium result with an RPD of 40.72, the result of a comparison of 7,390 pCi/L and 4,890 pCi/L.
- 12% of samples were collected in duplicate with 9% analyzed for inter-laboratory comparison and 3% analyzed for intra-laboratory comparison.

For tritium analyses, the MQOs for precision and duplicate sample collection have been met. Future sampling plans will need adjustment to meet the 5% intra-laboratory MQO.

4.1.4.2. Uranium-238

Figure G-23 provides inter-laboratory and intra-laboratory duplicate pair comparison results for uranium-238. The MQO established for uranium-238 requires that at least 85% of RPD results are acceptable or less than or equal to 30%.

- The duplicate pairs were analyzed using alpha spectrometry or ICP-MS with activities ranging from less than 0.1 pCi/L to 19.2 pCi/L.
- 94% of the duplicate pair comparisons were acceptable or had RPDs of less than or equal to 30%.
- Results outside MQO: 2, both intra-laboratory comparisons, one for laboratory B and one for laboratory G.
- 9% of samples were collected in duplicate with 3% analyzed for inter-laboratory comparison and 6% analyzed for intra-laboratory comparison. The percentage of inter-laboratory results are less than 5% because only intra-laboratory comparisons by laboratory G are possible for ICP-MS analyses.

For uranium-238 analyses, the MQO for precision was met. The overall MQO for percentage of duplicate samples collected, at 8.8%, did not quite meet the 10% MQO. Future sampling plans will be adjusted to meet the MQO. Meeting the MQO for inter-laboratory comparisons is unlikely due to the sole source for ICP-MS analyses.

4.1.5. Anions

Inter-laboratory and intra-laboratory duplicate pair comparison results for nitrate and perchlorate are discussed below.

4.1.5.1. Nitrate

Figure G-24 provides inter-laboratory and intra-laboratory duplicate pair comparison results for nitrate. The MQO established for nitrate require that at least 85% of RPD results are acceptable or less than or equal to 15%,

- The duplicate pairs were analyzed using EPA Method 300.0 with concentrations ranging from less than 0.44 mg/L to 710 mg/L.
- 98% of the duplicate pair comparisons were acceptable or had RPDs of less than or equal to 15%.

- Results outside MQO: 2, 1 inter-laboratory comparison between laboratories C and D with an RPD of 116, and one intra-laboratory comparison from laboratory A with an RPD of 82.
- 14% of samples were collected in duplicate with 9% analyzed for inter-laboratory comparison and 5% analyzed for intra-laboratory comparison.

For nitrate analyses, the MQOs for precision and duplicate sample collection have been met.

4.1.5.2. Perchlorate

Figure G-25 provides inter-laboratory and intra-laboratory duplicate pair comparison results for perchlorate. The MQO established for perchlorate requires that at least 85% of RPD results are acceptable or less than or equal to 20%.

- The duplicate pairs were analyzed using EPA Method 314.0 with concentrations ranging from less than 2 ug/L to 40 ug/L.
- 98% of the duplicate pair comparisons were acceptable or had RPDs of less than or equal to 20%.
- Results outside MQO: 2, both inter-laboratory comparisons.
- 12% of samples were collected in duplicate with 8% analyzed for inter-laboratory comparison and 4% analyzed for intra-laboratory comparison.

For perchlorate analyses, the MQOs for precision and duplicate sample collection have been met. Future sampling plans will be adjusted to meet the 5% MQO for intra-laboratory comparisons.

4.2. Field QC Duplicate Pair Comparison Results for 2021 Soil Samples

4.2.1. Volatile Organic Compounds

Figure G-26 provides intra-laboratory duplicate pair comparison results for VOC analysis of soil samples collected as part of the direct-push sampling survey in the Livermore Site TFD Helipad and East Traffic Circle North areas, and from other Livermore Site drilling activities. The MQO established for VOCs requires that at least 85% of RPD results are acceptable or less than or equal to 25%.

- The duplicate pairs were analyzed using EPA Method 8260 with concentrations ranging from less than 0.0034 mg/kg to 0.15 mg/kg.
- 99.7% of the duplicate pair comparisons were acceptable or had RPDs of less than or equal to 25%
- Results outside MQO: 1 intra-laboratory comparison of trichloroethene results with an RPD of 25.35. Only 5 intra-laboratory comparisons (approximately 2% of the total results) were between analyte concentrations (all trichloroethene) that exceeded the reporting limit. The duplicate pair comparisons were made between samples collected from slightly different depth intervals. For example, the duplicate pair from a depth of 140 ft consisted of a one sample collected from 140 ft and the other from 139.9 ft. RPD results that exceed the MQO may indicate more about subsurface heterogeneity than precision of the sample collection and analysis process.
- 7% of samples were collected in duplicate. For simplified logistics, the duplicate sample pairs were submitted for intra-laboratory comparison only.

For soil sample VOC analyses, the MQO for precision has been met. The percentage of duplicate samples collected, at 7%, did not meet the 10% MQO. Future sampling plans need to include more duplicate samples to meet the MQO.

4.3. Field QC Duplicate Pair Comparison Results for 2021 Air Samples

4.3.1. Volatile Organic Compounds

Figure G-27 provides intra-laboratory duplicate pair comparison results for indoor air samples collected for vapor intrusion monitoring at Livermore Site and Site 300, soil vapor samples collected as part of the direct-push sampling survey in the Livermore Site TFD Helipad and East Traffic Circle North areas, and routine soil vapor samples collected at Livermore Site and Site 300 for VOC analysis. The MQO established for VOCs requires that at least 85% of RPD results are acceptable or less than or equal to 25%.

- The duplicate pairs for indoor air vapor intrusion monitoring samples were analyzed using EPA Method TO-17 and the direct-push sampling survey soil vapor samples and routine soil vapor samples were analyzed using EPA Method TO-15. Concentrations for the indoor air samples ranged from less than 0.000024 parts per million by volume (ppm_v) to 0.00081 ppm_v. Concentrations for the soil vapor samples ranged from less than 0.005 ppm_v to 1.4 ppm_v.
- 99.5% of the duplicate pair comparisons (99.8% EPA Method TO-17, 99% EPA Method TO-15) were acceptable or had RPDs of less than or equal to 25%.
- Results outside MQO: 5, 1 unacceptable carbon tetrachloride result for indoor air vapor intrusion monitoring samples with an RPD of 30; 4 unacceptable results (2 for trichloroethene, 1 each for toluene and m- & p-xylenes) for soil vapor samples with a maximum RPD of 126.
- 13% of the indoor air vapor intrusion monitoring samples were collected in duplicate. Only intra-laboratory comparisons were possible because only one of LLNL's contact laboratories performs the required TO-17 analysis. 10% of the direct-push sampling survey soil vapor samples were collected in duplicate. For simplified logistics, the duplicate sample pairs were submitted only for intra-laboratory comparison. Only 1% of the routine soil vapor samples were collected in duplicate.

For indoor air vapor intrusion monitoring and the Livermore Site direct-push sampling survey, the MQOs for precision and duplicate sample collection have been met. Future sampling plans will require more duplicate samples for routine soil vapor sampling to meet the 10% MQO.

5. Representativeness

Representativeness, a qualitative parameter, means that the concentrations measured in the collected samples represent true site conditions and the actual concentrations of contaminants in groundwater, soil, or air. Lack of detections in trip blanks, field blanks, and equipment blanks are an indication that sample collection, handling, and equipment decontamination procedures did not introduce additional contaminants into the samples. Use of sampling techniques and methods appropriate to the well completion and hydrogeologic conditions, selected for each sampling location by staff hydrogeologists, also ensures representativeness of sample results. At the analytical laboratory, lack of detections in method blanks indicates contaminants are not added during sample preparation and analysis.

The lack of any significant detections in blank samples associated with water, soil, and air samples collected at Livermore Site and Site 300 during 2021 indicate that the analytical data are representative of site conditions.

6. Comparability

Comparability, a qualitative parameter, is achieved in the field by consistently following SOPs for sample collection, preservation, and handling. In the laboratory, comparability is achieved by consistently following the method-specified procedures for sample preparation and analysis. Certification to perform EPA-approved analytical methods, participation in performance testing programs, and regular assessments by Department of Energy Consolidated Audit Program–Accreditation Program (DOECAP-AP) and California Environmental Laboratory Accreditation Program (CA-ELAP) ensure the comparability of results obtained from different laboratories. RPD results from collocated field duplicate samples sent to different laboratories for inter-laboratory comparisons also serve as an indicator of data comparability. During 2021, the aforementioned requirements were satisfied and the MQO has been met.

7. Completeness

Completeness, a quantitative parameter calculated annually and expressed as a percentage of the quantity of samples that were collected and analyzed versus the quantity of samples that were planned to be collected, is determined by the following equation:

$$Completeness = \left(\frac{Number\ of\ samples\ collected\ and\ analyzed}{Number\ of\ samples\ planned}\right) \times\ 100$$

Samples that cannot be collected from locations that are dry or contain insufficient water for sample collection, or are inaccessible due to unsafe road/trail conditions, threat to wildlife, or institutional controls are not included in the completeness calculation.

During 2021, Environmental Restoration Department (ERD) field activities were conducted following LLNL's COVID-19 safety measures. However, ERD oexperienced several confirmed or suspected cases of COVID-19 that occasionally reduced the number of field personnel available to collect samples. Despite limited field personnel, completeness at both Livermore Site and Site 300 exceeded the 85% MQO.

Site 300

Overall completeness for Site 300 during 2021 was 94%. Approximately 3% (243) of planned samples were not collected because of limited personnel due to COVID-19. Taking the COVID-related limitations into account, completeness was 97% for Site 300. The 3% of samples not collected were from locations where equipment was inoperable or malfunctioning.

Livermore Site

Overall completeness for the Livermore Site during 2021 was 98%. Approximately 1% (36) of planned samples were not collected because of limited personnel due to COVID-19. Taking the COVID-related limitations into account, completeness was 99% for Site 300. The 1% of samples not collected were from locations where equipment was inoperable or malfunctioning.

8. Sensitivity

To be useful, data reporting limits must be lower than the MCLs or other established clean-up goals, particularly for the target analytes. The requested analyses used by LLNL have been established specifically to have reporting limits that are less than the MCLs or clean-up goals. Exceptions can occur when elevated concentrations of target and/or non-target analytes require sample dilution in order to stay within the method calibration range or prevent equipment damage. In these cases, the LLNL contract requires that multiple dilutions are performed to keep the higher concentration analytes within the method calibration range and achieve the lowest reporting limits possible for the other analytes.

During 2021, the analytical laboratories met the agreed upon bid package reporting limits and, when necessary, performed multiple dilutions to keep the higher concentration analytes within the method calibration range and achieve the lowest reporting limits possible for the other analytes. The use of different dilution factors by the laboratories resulting in different reporting limits that prevent useful comparisons of lower concentration results did occur occasionally. However, for the most part, the affected analytes do not have detection histories at LLNL and are not target analytes for the Livermore Site or Site 300 environmental restoration projects. Overall, the 2021 analytical data meet the requirement for sensitivity.

9. Analytical Laboratory Certifications, Performance Testing, and DOECAP Assessments

LLNL requires the analytical laboratories under contract to maintain CA-ELAP certification for all fields of testing applicable to LLNL samples and participation in nationally recognized performance testing programs. Participation in the DOECAP-AP, while not required, is desirable.

9.1. Analytical Laboratory Certifications

During 2021, all laboratories maintained CA-ELAP certification for the fields of testing applicable to LLNL samples. DOECAP-AP accreditation, for those labs participating in the program, was also maintained.

9.2. Analytical Laboratory Performance Testing

During 2021, labs participated in Performance Testing (PT) programs administered by Phenova, ERA, NSI Lab, Absolute Standards, Inc., Mixed Analyte Performance Evaluation Program (MAPEP), and LGC Standards. Unacceptable results for quantification of radium-226 in water were received by one laboratory from the MAPEP Radiological Water program during fourth quarter 2021. Follow-up testing is pending. Results from all other laboratories for methods and analytes of interest to LLNL were acceptable.

9.3. DOECAP Assessments

Due to ongoing pandemic-related travel limits, DOECAP authorized remote audit and assessment processes through January 2022. Effective October 28, 2021, all assessments were conducted to DoD/DOE QSM 5.4. Four of the analytical laboratories under contract to LLNL were assessed in March, August, October, and November:

March 29–April 2, 2021: The American Association for Laboratory Accreditation (A2LA), an approved accrediting body (AB) for the DOECAP-AP, conducted a remote renewal assessment of GEL Laboratories, LLC, Charleston, South Carolina. The assessment team noted 13 deficiencies. Upon receipt of acceptable corrective actions, the AB found GEL in compliance with the DoD/DOE QSM 5.3 and ISO/IEC 17025:2017 standards for their accredited scope, and DOECAP accreditation was maintained.

August 9–13, 2021: A2LA conducted an onsite renewal assessment of Eurofins Test America Denver, Arvada, Colorado. The assessment team noted 24 deficiencies. Upon receipt of acceptable corrective actions, the AB found Eurofins Test America Denver in compliance with the DoD/DOE QSM 5.3 and ISO/IEC 17025:2017 standards for their accredited scope, and DOECAP accreditation was maintained.

October 13–15, 2021: Perry Johnson Laboratory Accreditation, Inc. (PJLA), an approved AB for the DOECAP-AP, conducted a remote assessment of ALS Laboratory Group–Fort Collins, CO. Three nonconformities related to record-keeping were reported, none of which were repeats. The AB found ALS in compliance with the DoD/DOE QSM 5.3 and ISO/IEC 17025:2017 standards for their accredited scope, and upon receipt of acceptable corrective actions, maintained their DOECAP accreditation.

November 15–22, 2021: PJLA conducted an onsite assessment of BC Laboratories, Inc.–Bakersfield, CA (now known as Pace Analytical Bakersfield following their purchase by Pace in September 2021). There were 4 minor nonconformities related to requirements in recently released DoD/DOE QSM 5.4. DOECAP accreditation will be maintained upon receipt of acceptable corrective actions.

10. Internal Assessments and Inspections

DOE/LLNL conducts self-assessments, both formal and informal, to evaluate work activities to procedural, QA, management, and ISMS practices. External regulatory agencies and management also perform frequent assessments, verifications, and inspections of DOE/LLNL work activities. Due to COVID-19 restrictions, only four assessments were conducted for the Livermore Site CERCLA program during 2021, including a Storm Water Pollution Prevention Program (SWPPP) inspection, a Five-Year Review inspection, an annual institutional controls inspection, and one work observation of groundwater sampling. Sixteen assessments were conducted for the Site 300 CERCLA program during 2021, including a SWPPP inspection, two inspections of the Building 850 Corrective Action Management Unit (CAMU), seven inspections of the Pit 7 Drainage Diversion System (DDS), four inspections of the Building 829 monitor wells, an annual institutional controls inspection, and a Five-Year OU 2, 3, and 8 Review inspection. Issues and deficiencies observed during assessments are tracked from inception to resolution using the institutional issues tracking system. There were no deficiencies associated with the assessments performed for either the Livermore Site or Site 300 environmental restoration projects during this reporting period.

11. Summary and Conclusion

Overall, the 2021 analytical data met the MQOs established in the QAPP. Table 2 summarizes the 2021 results for analytical and field QC precision, accuracy, representativeness, comparability, completeness, and sensitivity assessed to the MQOs.

- There were only minor issues with analytical data that required rejection of the results during 2021. Data was lost for only one of the three samples with rejected VOC results, duplicate results were available and resampling was possible for the other two samples (Section 2).
- For accuracy, the overall results for each analytical group or specific analyte met the MQOs. Individually, all laboratories met the MQOs for VOCs, HE compounds, tritium, uranium-238, nitrate, and perchlorate. Individually, one of the three laboratories performing metals analyses did not reach the 85% MQO (Section 3.1).
- The MQOs for analytical precision were met by the overall results for each analytical group or specific analyte. Individually, all laboratories met the MQOs for HE compounds, metals, tritium, nitrate, and perchlorate. One of three laboratories performing VOC analyses (aqueous samples) and one of two laboratories performing alpha spectrometry analyses for uranium-238 did not reach the 85% MQO (Section 3.2).
- Field QC samples met their MQOs for precision, indicating good precision for the entire sample collection and analysis process (Section 4).
- The 10% MQO for duplicate sample collection was mostly met. Some improvement is needed, particularly for soil and soil vapor samples, and where possible, a more even distribution of samples for inter-laboratory and intra-laboratory comparisons (Section 4).
- There were no issues that would affect the representativeness, comparability, or sensitivity of the analytical data (Sections 5, 6, and 8).
- Completeness for Livermore Site and Site 300 was 98% and 94%, respectively, exceeding the 85% MQO. This was achieved despite a reduced number of sampling personnel due to confirmed or suspected cases of COVID-19 (Section 7).
- During 2021, the analytical laboratories fulfilled their contract requirements by maintaining their certifications, participating in PT programs with acceptable results for the analytical methods applicable to Livermore Site and Site 300 samples, and four laboratories retained their DOECAP accreditation after successful DOECAP assessments (Section 9).
- Due to COVID-19 travel and work restrictions, only self-assessments of internal operations and facilities were conducted during 2021. There were no deficiencies noted for the work observations and inspections conducted (Section 10).

In conclusion, the analytical data obtained from analysis of environmental samples collected by the Livermore Site and Site 300 environmental restoration projects during 2021 have met their MQOs and are of quality sufficient for their intended purposes.

Appendix G Table 1. Measurement Quality Objectives for Analytical Data.

Precision

	Analytical QC RPD Limit	*Field QC* RPD Limit	Requirement
VOCs	15	25	≥ 85% of results are acceptable* or ≤ RPD limit.
HE Compounds	25	35	≥ 85% of results are acceptable* or ≤ RPD limit.
Metals	10	20	≥ 85% of results are acceptable* or ≤ RPD limit.
Radionuclides			
Tritium	20	30	≥ 85% of results are acceptable* or ≤ RPD limit.
Uranium-238	20	30	≥ 85% of results are acceptable* or ≤ RPD limit.
Anions			
Nitrate	5	15	≥ 85% of results are acceptable* or ≤ RPD limit.
Perchlorate	10	20	≥ 85% of results are acceptable* or ≤ RPD limit.

Accuracy

	LCS Recovery	Requirement
VOCs	80-120%	≥ 85% of LCS recoveries.
HE Compounds	80-120%	≥ 85% of LCS recoveries.
Metals	90-110%	≥ 85% of LCS recoveries.
Radionuclides		
Tritium	80-120%	≥ 85% of LCS recoveries.
Uranium-238	85-115%	≥ 85% of LCS recoveries.
Anions		
Nitrate	90-110%	100% of LCS recoveries.
Perchlorate	85-115%	100% of LCS recoveries.

Representativeness

Detections in blank samples or other indications that representativeness of samples is compromised will be discussed in the annual Quality Assurance Summary.

Comparability

Any issues affecting the comparability of analytical results will be discussed in the annual Quality Assurance Summary.

Completeness

Both Livermore Site and Site 300: Analytical results are available for at least 85% of all planned sampling events.

At least 10% of all samples collected will have a collocated duplicate (1/2 (5% of total samples) sent for inter-laboratory comparison, the other 1/2 sent for intra-laboratory comparison.

Failures to meet this MQO will be discussed, along with corrective actions, in the annual Quality Assurance Summary.

Sensitivity

Any failures to meet required reporting limits will be discussed in the annual Quality Assurance Summary.

* Duplicate Results Comparison Guidelines

1) The standard RPD calculation is used when one or both results are greater than 5x the reporting limit.

2) When both results are less than 5x the reporting limit, results are acceptable when the difference between the results is less than or equal to the reporting limit.

3) When both results are less than the reporting limit, and the reporting limit is the same, the results are acceptable.
4) When both results are less than the reporting limit, but the reporting limits are different, the difference between 1/2 the reporting limits must be less than or equal to the smaller reporting limit to be acceptable.
5) When one result is a detection greater than the reporting limit, and the other result is less than the reporting limit (the reporting limits may be different), the difference between the detection and 1/2 the reporting limit must be less than or equal to the smaller reporting limit to be acceptable.

Appendix G Table 2. Measurement Quality Objective Results for 2021 Analytical Data.

Accuracy			
		MQO	**Result**
Aqueous Samples			
	VOCs	≥85% within 80-120%	MQO met: 95%
	HE Compound	≥85% within 80-120%	MQO met: 98%
	Metals	≥85% within 90-110%	MQO met: 96% overall, individually laboratory D with 78% did not meet the MQO.
	Radionuclides		
	Tritium	≥85% within 80-120%	MQO met: 98%
	Uranium-238	≥85% within 85-115%	MQO met: 100%
	Anions		
	Nitrate	100% within 90-110%	MQO met: 100%
	Perchlorate	100% within 85-115%	MQO met: 100%
Soil Samples			
	VOCs	≥85% within 80-120%	MQO met: 98%
Air Samples			
	VOCs	≥85% within 80-120%	MQO met: 96%

Analytical Precision			
		Analytical QC MQO	**Result**
Aqueous Samples			
	VOCs	≥85% acceptable or RPD ≤15	MQO met: 94% overall, individually laboratory D with 76% did not meet the MQO.
	HE Compound	≥85% acceptable or RPD ≤25	MQO met: 99.5%
	Metals	≥85% acceptable or RPD ≤10	MQO met: 98%
	Radionuclides		
	Tritium	≥85% acceptable or RPD ≤20	MQO met: 100%
	Uranium-238	≥85% acceptable or RPD ≤20	MQO met: 88% overall, individually laboratory E with 67% did not meet the MQO.
	Anions		
	Nitrate	≥85% acceptable or RPD ≤5	MQO met: 98%
	Perchlorate	≥85% acceptable or RPD ≤10	MQO met: 99.4%
Soil Samples			
	VOCs	≥85% acceptable or RPD ≤15	MQO met: 94%
Air Samples			
	VOCs	≥85% acceptable or RPD ≤15	MQO met: 99.8%

Field QC Precision			
		Field QC MQO	**Result**
Aqueous Samples			
	VOCs	≥85% acceptable or RPD ≤25	MQO for precision met: 97% acceptable results. MQO for 10% duplicate samples: 9% duplicates (6% inter, 3% intra)
	HE Compound	≥85% acceptable or RPD ≤35	MQOs met: 100% acceptable results, 13% duplicates (8% inter, 5% intra)
	Metals	≥85% acceptable or RPD ≤20	MQO for precision met: 88% acceptable results. MQO for 10% duplicate samples: 9.4% duplicates (4.5% inter, 4.9% intra)
	Radionuclides		
	Tritium	≥85% acceptable or RPD ≤30	MQO for precision met: 99% acceptable results. MQO for 10% duplicate samples: 12% duplicates (9% inter, 3% intra).
	Uranium-238	≥85% acceptable or RPD ≤30	MQO for precision met: 94% acceptable results. MQO for 10% duplicate samples: 9% duplicates (3% inter, 6% intra).
	Anions		
	Nitrate	≥85% acceptable or RPD ≤15	MQOs met: 98% acceptable results, 14% duplicates (9% inter, 5% intra)
	Perchlorate	≥85% acceptable or RPD ≤20	MQO for precision met: 98% acceptable results. MQO for 10% duplicate samples: 12% duplicates (8% inter, 4% intra).
Soil Samples			
	VOCs	≥85% acceptable or RPD ≤25	MQO for preccision met: 99.7% acceptable results. MQO for 10% duplicate samples: 10% direct-push soil samples, 6% other soil samples.
Air Samples			
	VOCs	≥85% acceptable or RPD ≤25	MQO for precision met: 99.5% acceptable results. MQO for 10% duplicate samples: 13% vapor intrusion monitoring samples, 10% direct-push soil vapor samples, 1% routine soil vapor samples.

Representativeness
No issues with detections in trip blanks, field blanks, or rinseates. Analytical data meet MQO.

Comparability
All requirements satisfied. Analytical data meet MQO.

Appendix G Table 2. Measurement Quality Objective Results for 2021 Analytical Data.

Completeness		
Project	**MQO**	**Result**
Livermore Site	≥85%	98%
Site 300	≥85%	94%
Sensitivity		
No issues during 2021. Analytical data meet MQO.
